Columbian Exchange

The early exchanges of life forms between Europe and America, which began in earnest with the voyage of Christopher Columbus in 1492, included disease germs, weeds, and vermin as well as medicines, crops, and domesticated animals. The effects were far-reaching for species that had developed in relative isolation on different continents of the Old and New Worlds.

Two hundred million years ago the continents of Earth were massed together contiguously. There was maximum opportunity for terrestrial species to migrate and therefore a higher degree of biotic uniformity than later. Then the continents split, drifted away from each other, and thereafter each continent's species evolved independently. North America and Asia reconnected several times in the far north and so share many species, but there are many contrasts between the two; the Old World, for example, has such native species as nightingales and cobras, which the New World does not share, while the New World has hummingbirds and rattlesnakes, not present in the Old World. Contrasts between South America and the Old World are especially dramatic; in the former one finds nose-wagging tapirs, whereas in the latter one finds nose-wagging elephants.

Old and New Worlds: People, Crops, Animals

Ten thousand years ago the most recent ice age ended, the continental glaciers melted, and sea levels rose, dividing the Old and New Worlds once again. Before that a number of species had passed between the two,

the most influential of which was the Old World anthropoid *Homo sapiens*. Thereafter the peoples of the Old World and the Americas evolved separately. The genetic differences that resulted were minor, but the cultural differences were major because the two peoples took different paths in exploiting their different environments.

Both invented agriculture—that is, the domestication of crops and of livestock—but two very different systems of agriculture. The Native Americans probably arrived from Asia with the dog and were therefore familiar with the concept of tame animals, but domesticated few creatures in America, possibly because there were few suitable. Those they domesticated included the llama and alpaca, the guinea pig, and several species of fowl. The Native Americans excelled as farmers, developing one-third or so of all of today's most important food crops: maize, beans of several kinds, the white and sweet potatoes, manioc (cassava), squashes and pumpkins, peanuts, papayas, guavas, avocados, pineapples, tomatoes, chilies, sunflower seeds, and others.

Not surprisingly, Old World indigenes, of whom there were many more than Native Americans and who lived in a wider expanse of land and participated in a greater variety of ecosystems, domesticated more kinds of animals and plants. Horses, donkeys, cattle, pigs, sheep, goats, chickens (today's protagonists of our barnyards and meadows and our chief sources of meat, milk, leather, and animal fiber) are all Old World in origin. The same is true of wheat, barley, rye, oats, rice, peas, turnips, sugarcane, onions, lettuce, olives, bananas, peaches, pears, and many other stock items of our diets today.

Honor sinks where commerce long prevails. • **Oliver Goldsmith (1749–1832)**

Separation of the Old and New Worlds: Disease

The Old World outdid the New as a source of infectious diseases, too. The greater number of people in more varied ecosystems were bound to have a greater variety of diseases, especially because they lived in close contact with their livestock. The intermixing of Old World humans across Eurasia and Africa, and their propinquity with their animals, produced many of the historically most significant diseases. An undoubtedly incomplete list includes smallpox, measles, influenza, malaria, yellow fever, and typhus. Pre-Columbian Amerindians had tuberculosis and treponematosi (having probably brought the latter with them from the Old World) and cultivated, unintentionally, new infections in America, including Chagas Disease, but their indigenous diseases were few and mild compared with those native to the Old World. (Syphilis is often nominated as a distinctively American infection, but that is debatable.)

When Christopher Columbus brought the Old and New Worlds together in 1492, he unleashed the organisms of each on the other. The most spectacular early result of the intermixing was the traumatic spread of Eastern Hemisphere infections among the Native Americans. The European conquest of the Americas was not so much a matter of brutality, though there was plenty of that, as of imported diseases. Smallpox figures significantly in the Spanish conquests of Mexico and Peru, and again and again throughout the Americas. The Native American population fell by as much, claim highly respected demographic historians, as 90 percent before beginning recovery.

On the other hand, Old World plants and animals immensely increased the capacity of America to support in time large human populations. Horses, pigs, and cattle, for instance, went feral from Florida to the Argentine pampa and within a century had propagated into the millions. Old World livestock revolutionized human life and whole ecosystems in the Americas. Meat had been a rare item in the diets of the vast peasantries of the advanced Amerindian societies. After the Columbian Exchange it became

common in many regions and in the others, if not common, at least more available than before.

There had been no beasts of burden in the Americas except the dog and the llama. The pyramids and other monuments of the high American civilizations were raised by human muscle. If the burro had been the only domesticated animal brought to Mexico by the invaders, it alone would have revolutionized indigenous societies there.

The impact of the horse on Native American societies was particularly spectacular. Many Amerindians who had been strictly pedestrian became equestrian. From approximately 1750 to 1800, the native peoples of North America's Great Plains (Blackfoot, Sioux, Cheyenne, Comanche, Pawnee, and others) and of South America's pampas (Pehuenches, Puelches, Tehuelches, Ranqueles, and others), all took to the horse.

Old World crops did not at first advance in the New World as rapidly as Old World livestock—they were, after all, not mobile—but also because most of them were temperate-zone plants not suited to Europe's earliest American colonies, which were all in the tropics. But European colonists adjusted, imported suitable species such as sugarcane, for instance, and suitable varieties of homeland crops, and sowed them where the soils and climates were similar to those at home. They discovered that wheat prospered in the Mexican high country, for example. Olive trees and grapes for wine did well in Peru. Within a century of Columbus most of the Old World's important crops were growing in America.

Among the most profitable was sugarcane, the source of a quasi-addictive substance: sugar. The market for sugar in Europe seemed endlessly expansive for centuries, and therefore sugarcane became the single most important crop in the West Indies, Brazil, and other hot, wet regions in or contiguous to the American tropics. The planting, cultivation, harvesting, and processing of the cane required millions of laborers. The Amerindian populations were plummeting, and European immigrants were in short supply. The workers had to come from some untapped source. The single most powerful force driving the Atlantic slave trade was the sugar plantations' need for laborers.

An estimated 12.5 million Africans were commandeered to work American soils, a majority of them, certainly a plurality, to raise an Old World sweet in the New World for Old World consumption.

1492 and the Old World

Amerindian livestock did not revolutionize life in the Old World. Guinea pigs and turkeys have never figured significantly in Europe, Asia, or Africa as food sources, and the llama was so obviously inferior to several Old World animals as a beast of burden that it has never had more than novelty value in the Eastern Hemisphere.

Amerindian crops, however, had enormous effect on the Old World. Most of those which became standard in Old World diets were brought back by the Spanish and Portuguese to Iberia, where they were being cultivated by the sixteenth century; they spread out from there. Some would flourish where Old World crops would not; manioc, for instance, where the rainfall was too much or too little, the soil infertile, and the pests too voracious for traditional staples like rice and yams. Several American foods were more nourishing, more productive, and easier to cultivate and to harvest than traditional Old World crops. Maize became a standard crop in sub-Saharan Africa, in some regions the most important crop.

The white potato, from the high, wet, cool Andes, became one of the most important food sources for the lower classes of northern Europe. In Ireland it became indispensable for the peasantry, and when, in the 1840s, an American fungus, *Phytophthora infestans*, arrived and destroyed the potato crop, a million died of starvation and disease and a million and a half fled the country.

The list of examples of the influence of the Columbian exchange in the Old World diets is a long one; it includes the tomato in Italian cuisine, the chili in Indian recipes, the presence of maize in most sub-Saharan African diets, and so forth. By way of illustrative example, let us consider the story of American food crops in a land usually thought of as resistant to outside influences: China. No Old World

people adopted these alien plants faster than the Chinese.

The eagerness with which the Chinese received American foods is related to population pressure. Between 1368 and 1644, the years of the Ming dynasty, the Chinese population doubled at the same time that farmers of the traditional staples, wheat in the north and rice in the south, were running into problems of diminishing returns. They were close to raising as much food as they could on suitable land using existing techniques. The problem may have been especially pressing in the south, where most of the level and near-level land close to markets and sources of water for irrigation was already occupied by rice paddies.

The Spanish and the Portuguese, both with American empires, carried the Amerindian crops to East Asia. The port of Manila, newly Spanish and only a few days' sail from the China coast, played a major role in the transfer of native American crops to China. Sweet potatoes, a calorically rich food, arrived in China some time in the last years of the sixteenth century. This crop did well in inferior soils, tolerated drought, resisted insect pests, and prospered with little care compared with existing staples such as

Mesoamerica developed edible varieties of maize as early as 5000 BCE. When maize arrived in China some 6,500 years later, it was valued as a fast-growing, high-caloric food source. Photo by Clara Natoli (www.morguefile.com).

paddy rice. By 1650 sweet potatoes were common in Guangdong and Fujian provinces and well on the way to becoming the staple of the poorer peasants wherever climate would allow.

Maize arrived in China even before the mid-sixteenth century. It, too, was hardy and required no more attention and strength in weeding and harvesting than children could provide. It produced food faster than most crops and provided high amounts of calories. It soon became a common secondary crop from Shanxi in the northwest to Yunnan in the southwest and eventually a primary crop in several inland provinces.

Peanuts, growing in China at least as early as 1538, have always been considered a novelty food in the West, but became a common item in Chinese meals. Peanuts provide plenty of calories and oil, and as they grow enrich the soil with nitrogen.

According to the demographic historian Ho Ping-ti, “During the last two centuries when rice culture was gradually approaching its limit, and encountering the law of diminishing returns, the various dry land food crops introduced from America have contributed most to the increase in national food production and have made possible a continual growth in population” (Ho 1959, 191–192). That statement applies as well to most of humanity in the Eastern Hemisphere.

Columbus, Christopher

(1451–1506)

EUROPEAN EXPLORER

History's portrayal of Christopher Columbus, which varies from hero to destroyer, often overshadows the man and his achievements. The European explorer who first set sail for the Americas in 1492 failed in his mission to find a route to the East Indies, but his journeys to the Americas sparked an era of unprecedented exchange between the Old and New Worlds.

Christopher Columbus is a tabula rasa, a blank slate upon which scholars of European overseas expansion inscribe their opinions about the significance of the man and the expansion. For some Columbus is a romantic figure, the last medieval crusader, whereas for others he is the first modern man, the man who first sloughed off the chains that had limited human development. People once saw him as initiating the civilizing and Christianizing process in the Americas, but now people condemn him for initiating slavery and genocide. His greatest claim to fame, however, is that he initiated the process that revealed the true nature of the Earth's surface and demonstrated that the seas are not an obstacle to worldwide communication but rather highways that can link all humankind.

All of these perceptions of Columbus mask the real man, obscuring his endeavors under a blanket of myths that reduces a complex individual to a stick figure. The difficulties involved in presenting the real Columbus are not, however, solely the responsibility of modern scholarship. The first person to generate a mythical Columbus was the explorer himself.

Columbus's early life is especially murky, a fact that has given rise to a number of imaginative theories about his origins. The best evidence, however, indicates that

he was born in Genoa, Italy, around 1451, the son of a weaver and his wife. Initially trained to practice his father's trade, Columbus went to sea, as Genoese men often did. He sailed much of the Mediterranean before moving to Lisbon, Portugal, where his older brother, Bartholomew, was a chart maker.

Lisbon was the goal for Genoese seamen, merchants, and bankers who were seeking new routes to the East to replace the colonies along the Black Sea that had once linked Genoa to the East but that were now in Muslim hands. Portugal attracted the Genoese because Portuguese sailors were sailing down the west coast of Africa and out into the Atlantic, where they had discovered four island chains: Canary, Cape Verde, Madeira, and Azores. To the Genoese these voyages held out the promise of

Christopher Columbus's voyages demonstrated that explorers could cross and recross the Atlantic in relative safety.

John Vanderlyn, *Columbus Landing at Guanahani, 1492* (c. 1837–1847). Oil on canvas.

finding a water route that would give them direct access to the markets of the Indies. In Portugal Columbus came to know the Atlantic as he participated in voyages to ports in the Gulf of Guinea, to the Azores, Ireland, perhaps even to Iceland.

Just as we cannot draw a precise map of Columbus's travels, we do not know the extent of his formal knowledge of geography and related matters. He claimed to have read the Roman scholar Pliny's *Natural History* and the works of contemporary cosmographers (scientists who study the visible universe) such as the Italian Paolo Toscanelli and the Venetian traveler Marco Polo, a copy of whose book Columbus annotated. He was also acquainted with the tradition that foretold the preaching of the Gospel to all humankind followed by the end of the world.

During the forty years preceding his first voyage, Columbus acquired a great deal of knowledge

about and experience of the Atlantic world, not all of which proved accurate. For example, he asserted that the circumference of the Earth is approximately 32,000 kilometers instead of 40,000 kilometers, the estimate that was accepted by some of his critics and that was close to accurate. His error was linked to his search for patronage: by accepting the smaller estimate of the Earth's size and by accepting the theory that the surface of the Earth is largely land, not water, he was able to make the notion of reaching Asia by sailing west more attractive. A short trip of a few weeks would bring him to the Indies.

Obviously, Columbus did not achieve what he set out to achieve, although he never accepted that fact. His four voyages to the New World—1492–1493, 1493–1496, 1498–1500, and 1502–1504—never reached Asia and never found the trade route that he sought. Seen in that light, he was a failure.

Seen in terms of world history, however, Columbus achieved a great deal. His voyages demonstrated that the Atlantic could be crossed and recrossed in relative safety. This fact in turn encouraged others to extend the range of exploring expeditions, eventually leading to the Spanish explorer Balboa's discovery of the Pacific Ocean in 1513 and then to the Portuguese navigator Magellan's fleet circumnavigating the globe during the period 1519–1522. These voyages showed Europeans the locations and size of the Earth's oceans and allowed ships to reach every shore except where Arctic and Antarctic ice blocked the way. New contacts multiplied, crops and diseases spread, and a new era of world history came swiftly on stream as sailors, colonists and conquerors collided with Amerindians and other previously isolated peoples around the Earth.

Columbus pioneered this new era; but his reputation has since fluctuated from heroic to hateful. After 1776 American revolutionaries toyed with the idea of treating him as the founder of their new nation, and named the District of Columbia accordingly. In 1893, the World's Columbian Exhibition at Chicago celebrated the 400th anniversary of his voyage whole heartedly. Then in the twentieth century, Italian immigrants began to parade on Columbus Day, claiming him as their own special hero. But

when the 500th anniversary came round in 1993, critics damped official attempts at celebration, accusing Columbus of responsibility for destroying the Amerindians and upsetting the natural balances of the New World.

Comintern

The organization called the Communist International, or Comintern, split from the Socialist International in 1919. Dominated by high-ranking members of the Russian Communist party, the Comintern initially set the goals of a worldwide proletarian revolution and the formation of an international Soviet republic, but it made subsequent decisions contradicting these aims.

The foundation of the Communist International, or Comintern (sometimes spelled Komintern), was officially proclaimed on 6 March 1919, at the Bolshoi Theater, Moscow, as the conclusion of debates at the First Congress of activists who refused the compromise position of the Socialist International controlled by reformist Social Democrats. Fifty-two delegates (thirty-four with a vote), predominantly from central and eastern Europe, and nominally from Asia and America, decided to create a Third International after what they denounced as the failure of the previous two Socialist Internationals, dominated by Social Democrats who had supported their respective countries during World War I.

The delegation of the host country included the highest-ranking members of the Russian Communist Party: Vladimir Lenin (1870–1924), Leon Trotsky (1879–1940), Joseph Stalin (1879–1953), Georgi Chicherin (1872–1936), Grigory Zinovyev (1883–1936), and Nicolay Bukharin (1888–1938), the latter two becoming the first two chairmen of the new organization. Owing to the extreme difficulty of travel because Bolshevik Russia was under attack by Western powers, other countries with a strong tradition of working-class militancy had only token representation. Thus Russians easily dominated The Congress

from the start. The agenda is probably best summed up by the concluding words of Lenin's inaugural speech: "The victory of the proletarian revolution on a world scale is assured. The founding of an international Soviet republic is on the way," (The Communist International 2004) but there was a fundamental ambiguity in the notion of an "international Soviet republic," because it could easily be interpreted as a republic subservient to Soviet Russian interests—an accusation that always plagued the Comintern.

The proceedings of the Second Congress (1920) led to the subsequent split in the world left between Communists—who adhered to the Comintern and its objectives—and Socialists, or Social Democrats, who rejected them. Many well-wishers from the Socialist ranks attended, but Zinovyev presented a list of twenty-one conditions to which adherents had to subscribe—many of them unacceptable to people who otherwise supported the Russian Revolution. All were asked to adopt the standard name, "Communist Party," and to accept Comintern decisions as binding, but the acid test was the adoption of "democratic centralism" as the governing principle of the Party in each country. In combination with the "dictatorship of the proletariat," this mode of functioning was found incompatible with fundamental freedoms by many existing left-wing organizations, who therefore declined to join the Communist International.

In a climate of extreme domestic and international bitterness, almost every developed or colonized country of the world then saw the creation of a Communist Party, side by side with the existing Socialist party or parties, whatever their names. The ideal of world revolution obtained by civil or foreign war, which was sustained by the continued agitation and/or military

Martyrs are needed to create incidents. Incidents are needed to create revolutions. Revolutions are needed to create progress. • **Chester Himes (1909–1984)**

A Soviet poster made by Ivan Vasilyevich Simakov in 1922 commemorated the fifth anniversary of the October Revolution and the IV Congress of the Communist International.

operations in Germany, Poland, and the debris of the Austro-Hungarian Empire, did not really abate until the final defeat of the German Communists in October 1923. The fiery anti-bourgeois language of Comintern affiliates fueled both the revolutionary enthusiasm of its adherents and the fears of established governments, including those with moderate left-wing majorities.

But then the Comintern instigated the first of the about-faces for which it became so notorious. At the Third Congress (1921), Lenin acknowledged that world revolution had not resulted from the “Imperialists’ War” (World War I) and that the Revolution could only be consolidated in Russia if the economy was modernized, notably with imports from capitalist countries. During the Fourth Congress (1922), Trotsky delivered an enthusiastic speech in favor of Russia’s New Economic Policy, but the rift was becoming evident between the continued supporters of world revolution (Trotsky and Zinovyev) and the advocates of “Socialism in one country,” led by Stalin and Bukharin after Lenin’s death in January 1924.

This was more than a personal quarrel, as the issue at stake was the orientation of the world Communist movement. In the end, Stalin’s views prevailed and in 1926 Bukharin (who was himself eliminated in 1929) replaced Zinovyev at the head of the Comintern, which became a mere instrument in Stalin’s hands in the furtherance of Soviet—some would say

Russian—interests. This is the period when Socialists were described as “Social Fascists” in Communist publications and speeches all over the world. Hitler’s ascent to power in January 1933 and fears of German aggression led to another radical about-face, with the Communist International now clamoring for a “united front against Fascism,” commonly called the Popular Front, by all progressive forces. In 1935, the Seventh (and last) Congress of the Comintern, now headed by the Bulgarian Georgi Dimitrov, gave its official sanction to this priority, which relegated world proletarian revolution—the initial purpose of the Third International—to a distant future. The final ideological blow came with the Nazi–Soviet Pact of August 1939, which technically made Communists worldwide the allies of Hitler, but the final dissolution of the Comintern came only on 22 May 1943, as a friendly gesture toward the Western allies of the Soviet Union in the “Great Patriotic War.”

Communication Media

Humans may have developed language as many as 100,000 years ago, fostering complex communication that far surpassed that of any other species. Since the invention of writing systems roughly 5,000 years ago, improvements in communication have been closely tied to changes in technology, from simple artifacts to elaborate equipment and complex networks that allow humans to transfer information over time and distance.

The term “communication” includes all the ways in which living beings convey information to one another. Plants and animals communicate by smell, sight, and sound. Human beings, with a limited sense of smell, communicate by sight and sound in far more complex ways than any other creatures. Not only have humans developed elaborate languages and gestures for face-to-face communication, they have also invented media such as writing and mechanical or electrical systems that transcend the constraints of time and space.

Human communication systems have had profound implications for world history. Language is the most important way in which humans have overcome their bodies’ limitations through culture, allowing them to spread into all the Earth’s environments. But language, writing, and other media have divided humans into rival groups and led to conflicts and the exercise of power by some people over others. For the past 5,000 years, improvements in communication have been closely tied to changes in technology, from simple artifacts to elaborate equipment and complex networks. Advances in technology have increased the efficiency of communication in

fundamental ways. Language has allowed humans to express complex ideas. Writing permitted communication at a distance and through time. Paper and printing diffused information widely, while the mass media has combined widespread with instantaneous diffusion. The Internet seems destined to offer the advantages of all earlier media, with the potential for transforming civilization in unforeseen ways.

Language

Speech is the original and only universal means of communication. All children learn to talk—except the deaf, who learn to sign—for language ability is innate in human beings. The six thousand languages spoken in the world today carry culture and provide identity, uniting people who understand each other and dividing them from those who speak another language. Yet anyone can learn any language, for there is no genetic predisposition for specific languages.

For centuries, people have known that some languages resemble one another: French, Spanish, and Italian are Romance languages, while Russian, Polish, and Czech are Slavic. It was also known that languages change over time, and that the Romance languages, for instance, all evolved from Latin. Beyond these obvious resemblances are more subtle affinities that only trained linguists can identify. In 1786 Sir William Jones, a judge in India, described the resemblances between Sanskrit, the ancient language of India, on the one hand, and Greek and Latin, on the other. He even asserted: “no philologist could examine them all three, without believing them to have sprung from some common source, which, perhaps, no longer exists” (Ruhlen 1994, 27). Linguists

Painting of a horse at Lascaux, France. People of the foraging era communicated by painting on the walls of caves or by carving pictures on rocks.

later proved Jones right by identifying Indo-European as the ancestor of most languages of Europe and India. Identifying affinities between seemingly distant languages and trying to reconstruct their common ancestors is the ongoing task of historical linguistics.

For over a century, linguists concentrated on demonstrating that the languages of Europe, Persia, and India form a great family called Indo-European. They also identified Semitic (Arabic and Hebrew), Bantu (the languages of central and southern Africa), Altaic (in central and northern Asia), Austronesian (in Southeast Asia and Polynesia), and other language families. Using painstaking techniques, they reconstructed the vocabulary of the long-vanished languages. Beyond that, they dared not go, for there seemed to be no resemblances between different language families.

Recently, however, bolder linguists have advanced the hypothesis that entire language families that seem unrelated actually belong to superfamilies and descend from a common ancestral tongue spoken tens of thousands of years ago. The boldest of all have advanced the idea that all the languages spoken in the world descend from a single original language—the “Mother Tongue”—spoken in Africa about 100,000 years ago.

Meanwhile, anthropologists studying ancient bones found that the first *Homo sapiens*, unlike earlier

hominids, had vocal cords capable of articulating words and minds able to carve sculptures and draw pictures: tantalizing clues to the complex thinking such as language requires. From the evidence of the bones, they deduced that *Homo sapiens* originated in Africa some 100,000 years ago and then migrated to other continents.

At the same time, geneticists were identifying the resemblances between the DNA of people on different continents. By doing so, they could determine the approximate length of time since two groups separated and where their ancestors came from. What they found is that *Homo sapiens* originated in Africa well over 100,000 years ago; some migrated to the Middle East around 100,000 years ago; they reached Southeast Asia about 80,000 years ago; New Guinea and Australia 50,000 years ago; Europe some 40,000 years ago; and the Americas 15,000 years ago (all figures give or take a few thousand years).

The findings of these three sciences, arrived at quite independently, are amazingly similar. What they tell us is that the language ability is unique to *Homo sapiens*; that the first language was probably spoken in Africa over 100,000 years ago; that humans dispersed throughout the world; and that as groups split up, their languages changed in different ways, producing the incredible variety that exists in the world today. Yet beneath that variety, the ability to learn and use language is the same all over the world, and all languages are equally capable of expressing the same range of ideas.

What caused the great variety of languages is separation. For millennia, as human groups dispersed, the differences between their languages increased. Before 10,000 years ago, when all people were gatherers and hunters who lived in small bands that rarely interacted, they must have spoken hundreds of thousands of different languages. Since the advent of agriculture and civilization, the trend has been reversed. Kingdoms and empires relied on communication and imposed a common language, if not on everyone, then at least on the educated. Several western European peoples speak languages derived from the language of the Roman Empire. Arabic is spoken from

The Incas of South America kept records of taxes and other transactions with knotted strings called *quipus*. Larco Museum Collection.

Iraq to Morocco, lands conquered by the Arabs in the seventh and eighth centuries. Most Latin Americans speak Spanish, most North Americans speak English, and many Africans learned the languages of their former colonial masters.

Though colonial empires have vanished, the spread of imperial languages continues. In fact, thanks to radio, television, business, and the press, it has accelerated. In Africa, schools teach children French or English or Portuguese. To prosper in a globalizing world, increasing numbers of people know they must speak not only their mother tongue but also a national or global language, and sometimes several.

The spread of national and global languages threatens linguistic minorities. Languages spoken by small numbers of people, such as indigenous tribes in the Americas, India, or Southeast Asia, are disappearing as young people turn increasingly to the languages of television, the press, the schools, and government, and see no reason to retain the language of the older generation. By the end of the twenty-first century, only half the languages spoken today will still be used. When languages vanish, so does much of the oral culture that they carry, such as tales, myths, and religious beliefs. Linguists are trying to record and transcribe as many of the endangered languages as they can before they disappear forever, but it is an uphill battle. Often the only people still fluent in an endangered language are old and cannot recall all

they once knew. As communication improves, the diversity of cultures in the world shrinks.

Visual Communication

Even before writing was invented, speech was only one of several means that humans used to communicate. People of the foraging era painted on the walls of caves or carved pictures on rocks. Such rock art is found in many places, the earliest in Namibia dating back 28,000 years, followed by the 16,000-year-old cave paintings of southern France, and many others, from the Sahara to Hawaii. Some archaeologists even speculate that Australian rock art may date back as far as 75,000 years ago. Neolithic people erected large stone monuments, such as Stonehenge in England or temples in Malta. The Olmecs of southern Mexico and the people of Easter Island in the Pacific Ocean carved gigantic stone sculptures. Such creations were works of art that served as ways of communicating ideas, as reminders of events, or as part of religious rituals.

Even more common than the artistic creations of prehistoric people are their mnemonic devices. Our world today is full of symbols that communicate and remind without the need for words: the silhouette of a person in pants and another one in a skirt indicate men's and women's toilets; a cigarette with a bar through it means "no smoking"; traffic signs can be grasped at a glance even by those who cannot read words. Mnemonic devices were among the earliest means of communication devised by *Homo sapiens*. Tally sticks with notches, found in the caves of Cro-Magnon peoples in France dating back 30,000 years, may have corresponded to the phases of the moon. Polynesian navigators made maps out of sticks and strings to help them remember the location of islands and to instruct their disciples. The Incas of South America kept records of taxes and other transactions with *quipus*, or knotted strings. And in Mesopotamia (now Iraq) and nearby regions, long before writing, people kept records of goods produced and exchanged with the help of tokens, bits of clay fashioned into different shapes that corresponded to

Communication leads to community, that is, to understanding, intimacy and mutual valuing. • Rollo May (1909–1994)

Library of Congress.

the items they represented (sheep, bushels of grain, jars of oil, and so on).

These are the physical objects that have survived or left traces for scientists to analyze. But like all people today, prehistoric people also must also have engaged in more ephemeral means of visual communication, such as gestures, facial expressions, songs, body movements, and dance. It is likely that they combined words, gestures, and music in religious rituals, storytelling, and dramas. The variety of ways in which humans could communicate with one another, even in prehistoric times, was almost limitless.

Writing

Writing is a means of inscribing words on a physical medium that can be preserved through time or transmitted from person to person. Full writing systems, capable of conveying any word in a language, appeared in several regions of the world at the beginning of their urban civilizations. The first was Sumer, in lower Mesopotamia, between 3300 and 3000 BCE. The script that the Sumerians created is called cuneiform, or wedge-shaped, because it was inscribed on clay tablets with the wedge-shaped end of a reed. Cuneiform writing and clay tablets were adaptable to many other languages in the Middle East and remained in use for 3,000 years. Tens of thousands of tablets have been found, almost all of them dealing with mundane matters of business, taxes, and administration. By the second millennium BCE, cuneiform was used to write literary texts such as the *Epic of Gilgamesh*.

The Egyptians, probably inspired by their Mesopotamian neighbors, created three writing systems. The best known is hieroglyphics, a combination of pictures and symbols that were carved on stone monuments and painted inside burial chambers and on important documents. Religious texts were written on papyrus, made from a reed that grew in the Nile delta, in a simpler script called hieratic. Everyday matters, such as business records or lists of words, were written in demotic, a kind of handwriting. Unfortunately, unlike the permanent clay tablets of Mesopotamia, almost all the papyrus documents have long since perished.

The Chinese began writing around 1500 BCE. Their first known writings were on bones used by soothsayers to predict the future. From the start, Chinese writing was logographic, meaning that each character represented a word. Though modern Chinese characters look different, scholars can trace their development from the earliest engravings to the present. It is by far the longest lasting writing system in the world, and suits the Chinese language admirably. Chinese characters were also adopted by Koreans and Japanese.

This telegraph key and register transmitted Samuel Morse's message "What hath God wrought" (Numbers 23:23) to his assistant Alfred Vail in 1844 along an experimental line between Washington D.C. and Baltimore. Photo by Alfred Harrell.

In the Americas, only the Maya created a full writing system, about 300 BCE. Like Egyptian hieroglyphics, it was pictographic and extremely complex. It was used in conjunction with the ancient world's most elaborate calendar to inscribe religious texts and the chronologies of kings and battles on temple walls. Mayan writing may have been based on Olmec systems dating back to the mid-second millennium BCE.

Today, most of the world uses alphabetic scripts. The first alphabet was devised by Semitic people in Egypt around 1800 BCE and spread from there to Palestine and beyond. Semitic alphabets such as Hebrew and Arabic include only consonants. Vowels are indicated by marks above the letters, but only in religious texts and in readings for children. When the Greeks adopted alphabetic writing from the Phoenicians in the eighth century BCE, they added vowels, which were necessary to express the Greek language. The Latin and Cyrillic (Russian) alphabets, used by a majority of the world's people today, are derived from the Greek.

Writing has been used for many different purposes: simple business documents, personal messages, monumental inscriptions, sacred texts like the Bible and the Quran, and works of literature and philosophy. For centuries, only a small minority—upper-class men, specially trained scribes, and a very few women—could read and write. Ancient economies were too limited to need much writing, and writing materials (except for clay) were too costly for most people.

More widespread literacy had to await the invention of paper and printing during the second millennium CE.

Postal Systems

Early writing systems were invented or adopted by government officials to keep records and communicate information and orders. Small states used messengers, but larger kingdoms and empires needed more reliable means of staying in touch with distant provinces. The Persians built the Royal Road from Susa, their capital in western Iran, to Ephesus on the Black Sea. Along it they established relay posts with fresh horses for royal messengers. The Romans built many roads and created an imperial messenger service, the *cursus publicus*. The Chinese, the Inca, and other empires found the same solution to the problem of administration at a distance.

Members of the public, however, had to find a traveler willing to take a letter to its destination. Only in the seventeenth century were postal services open to the public, at a very high cost. It was railroads, introduced in Britain in the 1830s and spreading to the rest of the world during the nineteenth century, that transformed postal systems from the exclusive privilege of the wealthy and powerful to the rapid, reliable, and cheap means of communication we are familiar with today.

Paper and Printing

Writing needed only simple artifacts and touched only a minority of people. To reach more people, communication had to be mediated by technology. The first in a series of ever more powerful communications media were paper and printing. Both were Chinese inventions. The earliest paper, made from hemp and ramie fibers, dates to the first century BCE. China was an extensive empire with a large literate elite that valued ancient texts and the art of calligraphy, and therefore used a great deal of paper. By the Song dynasty (960–1279 CE) there was an active trade in how-to manuals, novels, religious texts, and

Alexander Graham Bell speaks into a prototype of the telephone.

other books. The craft of papermaking spread from China to the Middle East in the eighth century and to Europe after the twelfth century.

What made paper truly useful was the invention of printing. Woodblock printing, in which a text was carved into a block of wood, originated in China in the eighth century CE and was used to print tracts, engravings, and paper money. Movable type made of ceramic appeared in the eleventh century, followed by metal type in the thirteenth. It was more widely used in Korea than in China, where woodblock predominated until the nineteenth century. In Europe Johannes Gutenberg (c. 1390–1468) reinvented movable metal type and printed a Bible in 1453; soon after the printing of all sorts of books, pamphlets, maps, posters, newspapers, playing cards, and much else contributed greatly to the expansion of literacy in the West as well as in East Asia.

Among the means of communication that printing permitted, the press became the most popular and influential, especially after the invention of steam-powered rotary presses in the early nineteenth century and the appearance of cheap tabloids a few decades later. Newspapers provided not only local news and useful information, but also stories from foreign countries slanted so as to inflame nationalistic passions.

Far from bringing about greater international understanding, the press raised popular enthusiasm for imperial conquests in the late nineteenth century and world wars in the early twentieth century.

Optical and Aural Signaling

The human voice only carries a short distance, and communicating in writing means transporting a physical object. In many parts of the world, people sought means of conveying information more rapidly over longer distances. Native Americans used smoke signals; tom-toms or drums were known in the Americas and in Africa; the Romans and medieval Europeans built towers on which fires were lit to warn of danger; ships used flags; and in 1775, Paul Revere hung lanterns in a church tower in Boston to warn of approaching British troops. All such signals had a weakness, however; they could only convey a few prearranged signals in one direction.

This changed during the wars of the French Revolution with the invention of two open-ended bidirectional visual communication systems: the optical telegraph and naval flag telegraphs. The optical telegraph, invented by the Frenchman Claude Chappe (1763–1805), consisted of articulated boards that could be moved into different positions to indicate either a code number or a letter of the alphabet. Starting in 1794, the French government placed such devices on towers throughout France and Napoleon's empire. Employees watched for signals from one neighboring tower and relayed it to another. On clear days, a message could travel from Paris to Toulon, 760 kilometers and 120 towers away, in twelve minutes. In night and fog, however, the system stopped.

At the same time and for the same reason—war—British naval officers transformed naval flag signaling from an occasional one-way message to a method of conveying any information between any two ships within sight of each other. At night, ships used lanterns with shutters. When the Napoleonic wars ended in 1815, these methods were quickly adopted by merchant ships and spread around the world.

Louis Daguerre, *Boulevard du Temple* (c.1839). The French government acquired Daguerre's patent for the Daguerreotype in 1839 and pronounced the invention a gift "free to the world."

Electrical Telecommunication

The telegraph and telephone are treated in detail in a separate article, so here we can give a very brief summary. The electric telegraph was developed in Britain in the 1830s and in the United States in the early 1840s. The American system, using a single wire and the code devised by Samuel Morse (1791–1872), was gradually adopted worldwide. An electric telegraph line cost less to build than its optical predecessor, could operate at night and in any weather, and sent messages much faster. So great was its capacity that it was opened to all users: railroads, governments, the press, and the general public. By the 1850s, telegraph networks covered Europe and the eastern United States. During the following decades, colonial powers erected telegraph lines in India and parts of Africa, as did independent nations in Latin America. The Chinese resisted for several decades, seeing it as an instrument of western penetration and espionage.

Meanwhile, engineers and entrepreneurs experimented with submarine telegraph cables to connect islands and continents into a global network. The first successful transatlantic cable began operating in 1866, followed in quick succession by cables to

India, Australia, and China in the 1870s, and around Africa in the 1880s. On the North Atlantic, competition reigned, but elsewhere, the cable business was monopolized by a few British firms. International and intercontinental telecommunication facilitated the expansion of trade and the flow of information around the world. It did not, however, lower the desire or reduce the opportunities for war as its pioneers had expected.

Unlike telegraphy, which had its greatest impact on long-distance communications, telephony was largely a local matter restricted, until well into the twentieth century, to businesses and wealthy people. The telephone was invented in 1876 in the United States by Alexander Graham Bell (1847–1922) and soon installed in all the major cities of North America and Europe. A transcontinental connection from New York to San Francisco was delayed for technical reasons until 1915. Only since World War II have telephone lines, and more recently cellular phones, spread to rural areas and developing countries.

Guglielmo Marconi (1874–1937) demonstrated the first wireless communication system in 1895. For the first twenty years, its use was restricted to sending telegrams in Morse code, while engineers concentrated on building ever larger transmitters to

communicate over ever longer distances with ships at sea and across continents and oceans.

Electronic Mass Communication

The nature of wireless communication changed radically when newer equipment began transmitting voices and music as well as dots and dashes. Broadcasting began with station KDKA in Pittsburgh in 1920. Two years later the United States had 564 commercial stations supported by advertisements. In most other countries, broadcasting was monopolized from the start by governments that used the new medium for cultural “uplift” and political propaganda. By the 1930s, shortwave radio broadcast political messages to foreign countries.

Television was technically feasible by the late 1930s, but its use in mass communication was delayed by World War II. It became a common consumer item in the United States during the 1950s and in Europe and Japan in the 1960s and 1970s. Though signals could only be broadcast locally, stations were connected by cables and the industry was dominated by three networks in the United States and one or two national networks in other countries. To prevent their citizens from watching foreign broadcasts, governments imposed mutually incompatible technical standards. In the 1970s and after, two new technologies—satellites and cables—challenged the entire system of national or commercial centralization, encouraging the proliferation of alternative information and entertainment media.

Motion Pictures and Sound Recording

During the nineteenth century, photography developed as a new art medium. At the end of the century, inventors in the United States and France found ways of projecting images in sequence so rapidly that the eye saw motion. Entrepreneurs soon found ways of presenting entire dramas on film, creating an industry that grew even more popular with the advent of talking pictures in the late 1920s and color films in the late 1930s.

Sound recording began in 1877 when Thomas Edison (1847–1931) recorded a voice on a cylinder. Ten years later, flat disks not only permitted the recording of music, but could be mass produced. After World War II, records were gradually edged out by magnetic tape and, since the 1980s, by compact disks and other digital media derived from computer technology.

Computers and the Internet

Until the 1980s, the mass media were unidirectional, with the public in the role of passive recipients. Computers made mass communication interactive on a global scale. This became possible when personal computers became affordable consumer items and even more when a gigantic decentralized network, the Internet, permitted the connection of any computer to any other. At first, the Internet operated like a free text-messaging service, but by the 1990s, the World Wide Web transmitted pictures, voice, and music as well as text. Businesses quickly seized upon the Web as a cheap means of advertising and selling their goods and services. Unlike radio and television broadcasting, however, neither business nor governments have been able to monopolize or censor the Internet. Individuals and organizations can transmit any kind of message or information to any interested party with access to a computer. What is emerging is a combination of personal and mass communication linking all parts of the world.

Although the price of computers and Internet service keeps coming down, this technology still benefits disproportionately the organizations and citizens of the wealthier countries. As of this writing, there are more computers and telephone lines in Manhattan than in all of Africa, and the gap is widening. Like their predecessors, the new communication technologies favor the elites, both locally and globally.

The Future of Communication

In the twenty-first century, communication systems will continue to expand and deepen their penetration

around the world. Cellular telephone and Internet access will reach even the most remote village. Newer media, such as wireless video-on-demand and virtual reality will supplement the media we know today. In the process, they will homogenize the world's cultures. Local languages will disappear, replaced by a few global ones. Tastes in clothing, music, and entertainment will converge. Yet, if past experience is a guide, better communications will not bring about better understanding between the peoples of the world or reduce the likelihood of wars. While technology gives us the power to send information across time and space at ever lower cost, it cannot prevent the abuse of such power by those who control the media.

Communism and Socialism

Socialist movements inspired by Karl Marx in late-nineteenth-century industrialized Europe sought to end class struggle and distribute goods evenly among the people. Communist parties forming in the early twentieth century in Russia and China argued that the key to industrialization was state ownership and planning. By the 1980s, the economies of major Communist countries were stagnating, clearly unable to compete effectively with more dynamic economies of the capitalist West.

An ancient vision of an ideal human community characterized by abundance, equality, freedom, cooperation, and harmony lies at the core of modern socialism and communism. Elements of this vision have surfaced repeatedly—in the message of the Hebrew prophets, in millenarian movements in Asia, Africa, and elsewhere, and in the small utopian communities of early-nineteenth-century Europe and America. (In general terms, communism refers to a political system that abolishes private property, and socialism to a system of collective ownership of the means of production and distribution.)

Marxism

Modern socialism took shape in the industrializing societies of western Europe during the nineteenth century. As a set of ideas, this socialism is forever connected to the writings of Karl Marx (1818–1883). Having witnessed industrial capitalism during its early and harshest phase, Marx set out to analyze that phenomenon and to chart its future development. Through the wonders of modern technology, Marx

argued, industrial capitalist societies had potentially solved the ancient problems of scarcity and poverty. They could now produce more than enough to meet the material needs of their citizens. In this sense, industrial capitalism was an enormously progressive development in human affairs, and he praised its achievements lavishly. But this vast potential was blocked by the fatal flaws of capitalism—private property, growing inequalities, bitter class conflict, worsening cycles of economic expansion and recession, competitive and individualistic values. Such societies, Marx believed, would self-destruct in a vast revolutionary upheaval, led by the factory working class (the proletariat), which was impoverished and exploited by the capitalist system. Then the vast productive possibilities of modern economies would be placed in service to the whole of society in a rationally planned and egalitarian community, bringing an end to class conflict, to national rivalries, and to the endemic poverty and inequalities of the past. This was socialism, and to Marx it marked the end of the sorry history of endless class struggle and opened the way to a bright and creative future for humankind.

Socialist Movements

Marx's ideas inspired socialist movements of workers and intellectuals amid the grim harshness of Europe's industrialization in the second half of the nineteenth century. Socialists established political parties in most European states and linked them together in international organizations. These parties recruited members, contested elections as they gained the right to vote, agitated for reforms, and in some cases plotted revolution. While established elites felt

An engraving of Karl Marx, whose writings provided the foundation for nineteenth-century socialist movements and twentieth-century communist regimes. Library of Congress.

enormously threatened by socialist movements, nowhere in the most advanced capitalist countries of England, Germany, France, or the United States did Marx's predicted revolution occur. Through democratic pressures and trade unions, workers gradually raised their standard of living while the beginnings of "welfare state" reforms softened the harsh edges of capitalism. Marx had not appreciated this capacity of capitalist societies to reform themselves. Furthermore, nationalism drew the loyalties of workers to their own countries rather than to the international working class, as Marx had imagined.

Socialist revolutions did occur in the twentieth century, but in places where Marx would have least expected them—in a Russian Empire just beginning to industrialize when the Communist regime came to power in 1917, in backward and impoverished China (1949), in a Cuba dependent on sugar production in 1959, and in Vietnam, which was emerging from

French, Japanese, and American imperialism at the end of the Vietnam War in the mid-1970s. In these countries, revolutionaries called themselves "Communists," to distinguish themselves from "social democrats" in the West who still continued to struggle peacefully through political processes. After seizing power, these Communist revolutionaries sought to "build socialism," which meant creating modern societies that were distinctly different from their capitalist counterparts. The Soviet Union under Joseph Stalin (ruled 1929–1953) and China under Mao Zedong (ruled 1949–1976) represent by far the most important examples of this process.

Putting Marxism into Practice

The first step involved the ending of old inequalities. Wealthy landowners had their property expropriated and distributed to the peasants. In China, teams of young revolutionaries were sent to the country's many villages, where they mobilized local peasants to confront landlords, to seize their property, and, not infrequently, to kill them. Privately owned industries were nationalized without compensation to their owners. Communist governments in both countries took immediate steps to guarantee equal rights for women within marriage and in public life, ending the legal disabilities that they had long suffered.

Since the Soviet Union and China were overwhelmingly agricultural societies, creating socialism in the countryside was a priority for both of them. The distribution of land to the peasants, although revolutionary, was hardly socialist because it left both countries with large numbers of small privately owned family farms. To Communist leaders, this was neither modern nor efficient, and it opened the door to a revival of capitalism and rural inequality as some farmers prospered while others became impoverished. The solution in both the Soviet Union in the late 1920s and early 1930s and China during the 1950s lay in large collective farms in which land, animals, and tools were held in common. The process of enlisting peasants into these collective farms unfolded with great violence and amid much resistance in the Soviet

The Kremlin, shown here in the 1880s, became the primary symbol of the Soviet Union in the twentieth century.

Union and was accompanied by a horrific famine caused by the heavy demands of state authorities for grain. The Chinese Communist Party, with deep roots in the rural areas, accomplished basic collectivization much more peacefully, though there too an enormous famine broke out in the late 1950s, when Mao Zedong pushed for even larger collective farms, known as communes, and for a more complete social equality. In both countries, the agricultural sector grew only slowly as it served to subsidize massive industrialization programs.

Communists everywhere were modernizers, intent on creating industrial societies. Furthermore, they argued that they had found a superior path to industrialization that would avoid the exploitation, instability, and inequalities of capitalism. The key to Communist industrialization was state ownership and planning. Under a series of five year plans, Communist planners decided where factories and mines would be located, what they would produce and in what quantities, where they would find their supplies, to whom they would sell their products, and at what price. After a fashion, it worked! Industrial growth rates in both the Soviet Union (1930s) and China

(1950s) were extremely rapid. The USSR in particular became a fully industrialized society in little more than a decade, strong enough to out-produce and defeat the Nazis in World War II.

But Communist industrialization also created a new elite of managers, bureaucrats, and technical experts who gained privileged positions in society, thus undercutting the supposed egalitarianism of socialist societies. While Stalin largely accepted these inequalities as temporarily necessary for modern development, Mao Zedong was increasingly troubled by them and launched repeated campaigns to root out materialism, self-seeking, and feelings of superiority in China's official elites.

Among the unique features of Communist societies was the extent to which party and state authorities penetrated and controlled the society. Since agriculture was collectivized and industry nationalized, virtually everyone was employed by state. Furthermore, the leaders of the Communist Party established the policies that the state bureaucracy was supposed to implement. Education served as a major vehicle for inculcating the party doctrines and Marxist thinking into the population. Organizations catering to the

interests of students, women, workers, and various professional groups were all controlled by the party. The multitude of private voluntary organizations that characterize democratic capitalist societies had no counterpart in Communist countries.

The Search for Enemies

But the Communist societies of the Soviet Union and China were laced with conflict. Under both Stalin and Mao, those conflicts erupted into a search for enemies that disfigured both societies. In the Soviet Union that process culminated in what became known as the Terror of the late 1930s, which affected tens of thousands of prominent Communists, including virtually all of Lenin's top associates, and millions of more ordinary people. Based on suspicious associations in the past, denunciations by colleagues, connections to foreign countries, or simply bad luck, these people were arrested, usually in the dead of night, then tried and sentenced either to death or to long years in harsh and remote labor camps known as the Gulag. Close to a million people were executed between 1936 and 1941. Perhaps four or five million more were sent to the Gulag, where they were forced to work in horrendous conditions and died in appalling numbers. Victimizers too were numerous as the Terror consumed the energies of a huge corps of officials, investigators, interrogators, informers, guards, and executioners.

While the search for enemies in the Soviet Union occurred largely in secret and under the clear control of the state, in China it became a much more public process, particularly during the Cultural Revolution of 1966–1969. Mao became convinced that many within the Chinese Communist Party itself had been seduced by capitalist values of self-seeking and materialism and were no longer animated by the idealistic revolutionary vision of earlier times. And so, he called for rebellion against the Communist Party itself. Millions of young people responded and, organized as Red Guards, set out to rid the country of those who were “taking the capitalist road.” The outcome was chaos and violence that came to the edge of civil war,

and Mao found himself forced to call in the military to restore order and Communist Party control. Both the Soviet Terror and the Chinese Cultural Revolution badly discredited the very idea of socialism and contributed to the ultimate collapse of the Communist experiment at the end of the century.

The End of the Communist Experiment

The demise of world Communism was both rapid and largely unexpected, and it occurred in various ways. In Eastern European countries, where Communist governments had been imposed by Soviet military force after World War II, popular movements in 1989 swept away despised governments with stunning rapidity. The dramatic breaching of the Berlin Wall, which had long separated East and West Berlin, became the enduring symbol of these movements. In the USSR, Mikhail Gorbachev's efforts to reform Communism (1985–1991), reducing state control over the economy and permitting unprecedented freedom of expression, backfired badly. His reforms sent the economy spiraling downward and stimulated nationalist and anti-Communist movements that led to the complete disintegration of the country itself in 1991 and the repudiation of its Communist Party. In China, the Chinese Communist Party retained power but abandoned many Communist economic policies during the 1980s and 1990s, such as ending collectivized agriculture, and began to permit massive foreign investment and allow many private or semiprivate businesses to operate freely. These reforms sparked an enormous boom in the Chinese economy that contrasted sharply with the economic disasters that accompanied the disintegration of the Soviet Union.

Scholars continue to debate the reasons for the quite sudden end of the Communist era in world history. In large measure, the fundamental failure of Communism was economic. By the 1980s, it was apparent that the economies of major Communist countries were stagnating, clearly unable to compete effectively with the more dynamic economies of the capitalist West. This perception drove the reform process in both the Soviet Union and China. A further

Of course, we do not want socialism in Latin America to be an imitation or a copy. It must be a heroic creation. We must inspire Indo-American socialism with our own reality, our own language. That is a mission worthy of a new generation. • José Carlos Mariátegui (1894–1939)

factor was the erosion of belief. An earlier idealism about the potential for building socialism had largely vanished amid the horrors of Stalinism and Maoism, replaced, especially in the USSR, by a self-seeking cynicism.

The collapse of Communism, like its revolutionary beginnings, had global implications. It marked the end of the Cold War, which had dominated international life in the second half of the twentieth century and had threatened a nuclear holocaust. As the bipolar structure of the Cold War era faded away, the United States emerged as the world's single superpower, bringing with it new charges of an American global empire in the making. Furthermore, the end of Communism signaled the closure of a century-long global debate about socialism and capitalism as distinct and rival systems. Market economies and capitalist ideologies had triumphed, at least temporarily. In Eastern Europe and more tentatively in the former Soviet Union, the demise of Communism also allowed the flowering of more democratic political systems. Despite the continued dominance of Communist parties in China, Cuba, Vietnam, and North Korea, expectations of a socialist future had largely disappeared everywhere and the Communist phenomenon in world history had ended.

Comparative History

The comparative historical method, first introduced by the French scholar Marc Bloch, stresses the idea of a common universal history among even the most unrelated of societies. For example, although a revolution arises out of a distinctive historical situation, revolutions in general share certain traits that account for their dramatic political changes. This method requires historians to take a more global approach to their work.

Many modern historians rooted in their fields of time and place defend the uniqueness of the events, institutions, and processes they study. Sometimes they neglect to recognize, however, the ways in which their explanations and interpretations depend on principles of understanding that connect what they see in their particular cases to other phenomena. The uniqueness asserted by historians is often of a phenomenon that is itself broken down into parts that we understand because they resemble familiar ideas and practices from other times and places. The explanations and interpretations in all case studies depend in various ways on certain general principles that are themselves distilled from comparisons among other historical experiences. Comparative history, a field that focuses mostly on relatively recent history (i.e., beginning about 1500 CE), involves more explicit comparison, one that consciously identifies both similarities and differences.

The European Context

One of the first historians in the twentieth century to stress the importance of the comparative historical

method was Marc Bloch, the great French scholar of medieval and early modern Europe. In an essay entitled “A contribution towards a comparative history of European societies,” published in 1928, Bloch identified two main contexts in which comparisons are an important tool for historians. First, he noted that in widely separate places in early history there seemed to be similar practices among what he called “primitive peoples.” Studies of early cultures conducted in the 1920s interpreted such similarities as signs of a common universal history. The second context for using a comparative method, and the one to which he devoted most of his attention, involves areas close to one another where mutual influences or common origins for ideas and institutions are obscured by linguistic differences and national historiographical traditions. Bloch argued that the study of feudalism and manorial organization, for example, must span Europe generally rather than just one European nation, since the similarities and differences among practices suggest a range of related practices common to many places. According to this view, focusing only on French or German cases might lead the researcher to look for local explanations for practices that in fact were the result of more widely applicable factors in European society.

In another essay, “A Problem in Comparative History: The Administrative Classes in France and Germany,” also published in 1928, Bloch analyzes feudal political relationships and uncovers both similarities and differences, in the process identifying what he considers features of German law that are significantly different from other legal systems in central and eastern Europe.

The Global Context

More recent scholarship on both political and economic history has employed comparative methods to analyze historical change within Europe and on a more global scale. Some scholars have looked at particular categories of complex events, like revolutions. Theda Skocpol's widely read *States and Social Revolutions* (1979) presents a series of similarities and differences among the French, Russian, and Chinese revolutions to argue that revolutions, although each arises out of a distinctive historical situation, share certain traits that account for their dramatic political changes. Another text, Jack Goldstone's *Revolution and Rebellion in the Early Modern World* (1991) identifies a series of common problems in England, France, China, and the Ottoman Empire that create similar crises from which emerge distinct patterns of rule. Large revolutions are few in number, and plausible comparisons are therefore limited. Larger numbers of comparisons become possible when political changes more generally are studied.

Charles Tilly (1975, 1992) explains the formation and transformation of European states since roughly 1000CE according to the relative abilities of rulers to amass resources and make war. Beginning amid a tremendous diversity of political units, in Tilly's account, some states stress mobilizing commercial revenues while others are better able to build armies by taxing the land. By the seventeenth and eighteenth centuries, the most successful states are those that can both gain wealth and monopolize the use of force. Tilly's work suggests variations among European states in a dynamic process of political transformations.

Another influential approach to the formation of modern states highlights the changing bases of political authority in societies with hereditary rulers and in societies in which rulers appeal to their subjects for legitimacy. Reinhard Bendix (1978) has studied changing authority relations between states and subjects as the key axis along which to observe the turn toward modern states in which people achieve popular sovereignty. Like Tilly, Bendix portrays variations among countries that all undergo parallel

processes of political change. Both scholars also recognize connections among their cases: Tilly's polities are all part of a larger European state system, and Bendix tracks the spread of ideas and institutions basic to modern states from their points of origin to other places. Bendix's approach takes him beyond his European cases of England, France, Germany, and Russia: he analyzes Japan as an example of a country to which political concepts first forged in Western Europe subsequently spread.

In contrast to studies that remain within Europe or explore the export of practices from the West to other regions, Victor Lieberman (1997, 2004) has suggested that similar processes of change were taking place between the mid-fifteenth and mid-nineteenth centuries across the East–West divide; he compares Burma (Myanmar), Siam (Thailand), and Vietnam with France, Russia, and Japan, arguing for similar processes of political, economic, and cultural changes in each case. Lieberman's identification of parallel dynamics of political and social change within and beyond Europe has been an important contribution to reframing the discussion about European historical change.

Complementing Lieberman's insights is another approach to the particularities of European state formation that contrasts the European examples with the dynamics of political evolution in another major political system, the Chinese agrarian empire. R. Bin Wong has shown that the challenges faced by state-makers in Europe were in many ways distinct from those confronting Chinese rulers. According to Wong (1997, 2002), the responses to these challenges were influenced in Europe by the claims elites could make upon their rulers, whereas in China they were guided by the common commitments rulers and elites made to sustain social order.

Overseas colonial empires represented yet another kind of state that defined a set of relations between a metropole and its periphery. Nineteenth-century colonialism suggests a different way in which European states reached other parts of the world: not as the benign purveyors of political principles and models of government, but as overlords who divided

up large parts of Africa and Asia as an extension of state competition in Europe. According to Lauren Benton (2002), these competing colonialisms produced a range of similar developments, including the introduction of various forms of pluralism as a means to accommodate cultural differences—sometimes in ways that led to an acceptance of colonial rule in many nineteenth-century colonies.

Learning from European colonization programs, the Japanese state began to build its own colonial empire in the late nineteenth century. The Japanese results, however, were different from the colonial empires of Western powers, which had their colonies spread over vast distances. The Japanese colonial empire, beginning with Taiwan and Korea and later Manchuria, was viewed by many in the Japanese government as a tightly knit regional political and economic order designed to support Japan and secure it from threats posed by Western powers. From an east Asian perspective, the Japanese Empire represented the creation of a new kind of political order replacing the much looser symbolic order of tributary relations centered on the agrarian empire. In place of ritual presentations of tribute and commercial exchanges under the tributary order, colonial empire imposed legally defined and bureaucratically organized control over subject populations who were subjected economically to extractive and unequal relationships to the colonizer. Both Chinese agrarian empire and Japanese colonial empire differed from European empires in two ways—first, Europeans competed with each other and divided territories among themselves in different world regions; and second, the distances from imperial center to periphery were far longer for Europeans than in East Asian cases. Neither the Chinese world order nor the Japanese colonial empire that succeeded it were simply subordinated to a Europe-centered system of international relations; rather, a unique and evolving system of regional political relations persisted among East Asian states even as they became more connected to the powerful political and economic system centered on both sides of the Atlantic. Such hemispheric distinctions suggest that interpretations of modern political change as exclusively or even primarily the

expansion of a Western system of international relations are incomplete and misleading.

Assessing the Europe-Centered Approach

These interpretive difficulties notwithstanding, much influential work in world history has been done by tracing the expansion of European power across the globe—in fact, historians have tended to view nineteenth- and twentieth-century international relations as the most recent chapter in a story of Western political and economic domination. Most all interpretations of large-scale changes largely build upon directly or indirectly the work of Karl Marx and Max Weber. The systemic features of this European expansion form the basis of Immanuel Wallerstein's modern "world-system" (1974, 1980, 1989). Wallerstein's seminal work, inspired by Marxist insights, makes brief comparisons between the international system centered on the European world from the sixteenth to the mid-nineteenth centuries and systems in place elsewhere in the world, before asserting that by the end of the nineteenth century, any fundamental East-West distinctions were subordinated to what had become the modern, Western-dominated world-system. Therefore, most analyses inspired by Wallerstein's work focus on the Europe-centered system and its expansion, without much attention to the dynamics of change within other systems.

Part of the intellectual foundation of Wallerstein's world-system is the work of French historian Fernand Braudel, one of whose major studies, the three-volume *Civilization and Capitalism: 15th–18th Century* (1992), identifies the distinctiveness of European capitalism through comparisons with merchants and markets in different parts of Asia. Such comparisons follow a long tradition of efforts by seminal thinkers to explain the distinctiveness of Europe and its patterns of political and economic transformation by identifying contrasts with non-European parts of the world. In the nineteenth century most observers, including revolutionary figures like Karl Marx, believed that outside Europe lay stagnant societies with unchanging economies. Most educated

Westerners exposed to cultures in Africa and Asia regarded these places as inferior to the West; while some were recognized as descendants of great and powerful ancient civilizations, on the whole they were seen as shallow and broken remnants of their past greatness.

Max Weber, the early-twentieth-century master of historical comparisons, looked to religion and ethics as the arena in which different attitudes toward money and markets took shape. He noted that in the Christian West, these attitudes formed in a way that led to the rise of capitalism, while in other religious traditions they did not (1958). Weber's famous observations about a "Protestant work ethic" have been qualified, however, by more recent scholarship documenting what appear to be functionally similar beliefs in other religious traditions (e.g., Bellah 1957; Rodinson 1974). Comparisons of a broader and more general kind between Europe and other parts of the world have continued to highlight differences, whether formulated within a clear Weberian framework (Hall 1985) or presented in a more ad-hoc and storytelling manner (Landes 1998).

Marxist interpretations have also argued for distinctive European political and economic practices, as shown in two influential works of the 1970s. Perry Anderson's two-volume study of European state formation, *Passages from Antiquity to Feudalism* and *Lineages of the Absolutist State* (1974), went back to classical antiquity to give a long-term view of how absolutist states were formed centuries later; his appendices on China, Japan, and the Ottoman Empire reviewed much of the available research to suggest how a Marxist analysis of these cases could be fashioned to complement what he had done for Europe. Robert Brenner also wrote an influential study comparing English agrarian social relations with those on the European continent (1976); he argued that it was English social relations that made possible increased agricultural productivity and surpluses that financed the formation of commercial capitalism. After his conclusions were challenged by English, French, and Dutch data, Brenner shifted his arguments from class relations to the late medieval state (1982) and later to an explanation specifically of

Dutch materials (2001). More recently, in work with Christopher Isett (2002), Brenner has returned to his initial formulation about agrarian class relations and gone well beyond Europe to look at an economically active part of eighteenth-century China, attempting to argue that differences in social relations cause differences in agricultural productivity.

The Brenner-Isett effort is part of a debate with Kenneth Pomeranz over explaining what the latter has called the "great divergence" between Europe and the rest of the world (Pomeranz 2001). Pomeranz shows similarities in the performance of the advanced agrarian economies in Asia, especially China, and in Europe; in order to explain the subsequent divergence in economic fortunes, he stresses Europeans' economic gains, especially in terms of resources, from the particular ways in which they developed production in the Americas. On the other hand, where Brenner and Isett affirm different agrarian social relations as basic to differences in trajectories of economic change, David Landes stresses what seem largely cultural factors. Together Brenner, Isett and Landes affirm the continued contemporary appeal that the ideas of Marx and Weber have for historians who make broad comparisons among large parts of the world.

A distinct addition to these comparisons is highlighted by Andre Gunder Frank, who aggressively argues (1998) for connections among the world's economic regions and asserts that China was at the center of the world's economy between 1500 and 1800, taking in large amounts of silver to fuel its expanding commercial economy. In contrast, R. Bin Wong suggests that the economic links made possible by the silver trade did not encourage the kinds of division of labor and movements of capital and labor that would come to characterize international trade after the mid-nineteenth century; he argues that a comparison of the early modern world economy with what follows offers important differences as well as parallels (Wong 2002).

Beyond the East–West Divide

Many uses of the comparative method in historical studies occur across the East–West divide of Eurasia.

But there have also been comparisons that set this vast land mass off from still other continents. The anthropologist Jack Goody has argued that societies across Eurasia, from Japan to England and most points in between, shared structurally similar kinds of kinship systems, demographic regimes, and social structures. For him the major divide globally is between Eurasia and sub-Saharan Africa, where kinship and social structures differed from those of Eurasia largely due to small populations relative to land and the implications of this situation for techniques of economic production and social control (1971, 1976). Within this broad framing he has repeatedly criticized ideas about European uniqueness (1990, 1998).

Jared Diamond has drawn a related contrast between Eurasia and other continents in *Guns, Germs, and Steel* (1997), suggesting that Eurasia had a geography well-suited to farming and animal domestication; this in turn supported more densely populated areas where more complex governments, sophisticated systems of communication, and increased resistance to diseases all developed. Diamond has very little to say, however, about the causes of variations within Eurasia, the terrain across which historians making comparisons have usually moved. The great sweep of Diamond's history across space and through time depends on some basic comparisons between environmental and biological traits of Eurasia and other continents. Many books on environment and biology in world history, like Alfred Crosby's *Ecological Imperialism*, stress connections made by European expansion rather than comparisons among different cases. Yet, common themes in environmental history can be seen through comparisons, as John Richards demonstrates in *The Unending Frontier* (2003). This history of the environment of the early modern world includes comparisons of agricultural settlement patterns on Taiwan, mainland China, and Russia; land use patterns in the Americas; and the hunting and fishing industries.

Comparative methods have been used implicitly or explicitly in historical studies for a long time. Explanations and interpretations of a particular phenomenon depend on comparing the case at hand

with more familiar examples of the same or at least similar phenomena. Among historical works that are explicitly comparative, certain European experiences have often been taken as a benchmark against which to measure performance elsewhere. Whether Marxist or Weberian, this approach has motivated the search for similarities and differences between European patterns of political, economic, and social change and those in Africa, the Americas, and Asia. Many such efforts stress the differences that make Europe the historical paradigm, while others argue, in a related fashion, that historical change elsewhere in the world influenced by European principles and practices tends to result in comparable outcomes. Critics of what is usually a cheerful view of convergence often contend that Western expansion has been destructive, putting many populations into subordinate economic and political conditions. Yet, many recent historical comparisons have also moved beyond simple dichotomies, highlighting in more nuanced ways both similarities and differences and the way they interact to produce unique historical outcomes.

Confucianism, based on teachings of the Chinese philosopher Confucius (551–479 BCE), has inspired philosophers and statesmen for more than 2,500 years. It stresses the importance of education for moral development—humane relationships, good intentions, and decorum, as well as loyalty and trustworthiness—so that rulers can govern the state according to virtue rather than coercive laws.

Confucianism, a social and ethical philosophy rather than a religion, originated with Confucius (551–479 BCE), whose name represents a Latinized version of the title Kong Fuzi (Kong the Grand Master). With Daoism and Buddhism, it was one of the three ways of thought in traditional China. The era in which Confucius lived was one in which other major philosophers and founders of religious traditions also lived, including Siddhartha Gautama (the Buddha, c. 563–c. 483 BCE) in India, Zoroaster (c. 628–c. 551 BCE) in Iran, the Hebrew prophets in Palestine, and Thales (627?–547 BCE.) in Greece. He shares with these figures the role of defining the classical heritage of the subsequent civilizations in those regions. In response to conditions of large-scale warfare, diasporas, and rapid social change, all five eras produced humankind's first conscious responses to factors of global impact. The responses were ethical in nature and shared a human-centered belief in the human ability to forge new answers. The parallelism of developments in these five areas, constituting as it does a distinctive world epoch (which the philosopher Karl Jaspers called the Axial Age) intrigues the historical imagination to this day.

Early Confucianism

Confucius first sought ministerial rank in Lu, one of numerous states constituting a not-yet-unified China. Failure at that turned him toward teaching. It is as a teacher that he was remembered, and a philosophy of statehood (sponsored by the state) formed around his teachings. He initiated three traditions: teaching any who would learn (the democratic temper), being a private teacher (education for its own sake), and valuing the transforming influences of history, arts, letters, and music (liberal education).

Confucius wrote no books, but his teachings are gathered in the *Analects* (*Lunyu*), a collection of 479 sections of sayings attributed to him by three generations of students and disciples. Disparate in subject, timeframe, and personal nuance, the work is unified by the fact that all its utterances have to do with Confucius. This work stands at the center of the Confucian tradition, not only in China but in the entire eastern Asian context. The seventeenth-century Japanese Confucian thinker Ito Jinsai called it the most profound book in the universe.

Basic Principles

The three principal ideas in the *Analects* are *ren*, *yi*, and *li*. *Ren* means interpersonal humane regard, from which flows the entire Confucian social philosophy, in which a person sees his or her own humanity in another person. *Yi* is the impulse to do the right thing, to be *ren*. *Li* (social ritual) is the composite of all decorum and manners from the mundane to the loftiest of rites, the outward manifestations of *ren* and *yi*. These qualities underlie the Confucian interpersonal

A carved stone guard at the Temple of Confucius at Qufu in Shandong Province, the legendary birthplace of Confucius. Photo by Joan Lebold Cohen.

philosophy, and, along with the important qualities of trustworthiness (*xin*) and loyalty (*zhong*), give life to his view of state and society as consisting of the five cardinal relationships: ruler-ruled, father-son, husband-wife, elder brother-younger brother, and friend-friend. Confucius viewed the family as the microcosm of the state and the state as the macrocosm of the family. His philosophy is this-worldly. When queried about his view of religion and the spirits, he said, “Not yet serving humans, how can one speak of serving the spirits” (*Lunyu* [analects], *xianjin* [chapter]).

Mencius and Xunzi

Early Confucianism depended on the thinking of two other philosophers: Mencius (385–303/302 BCE) and

Xunzi c. 298–c. 230 BCE), disciples of Confucius who lived some two hundred years after the master. Each with a work carrying his name, the two propounded the idealistic and realistic tendencies, respectively, inherent in the master’s teachings. Both works are examples of elegant Chinese prose. Mencius argued philosophically that human nature was innately good. From this premise, the Mencian program for humanity valued persuasion over coercion, exemplary action over dictated rules, and moral factors over utilitarian motives. Mencius appreciated the people as arbiter of moral rule, and in a three-tier order of importance, ranked them above the agrarian economy and the ruler. From this ordering, subsequent generations derived justification for a right of the people to rebel.

Mencius’s contemporary, Xunzi, on the other hand, argued that human nature was rapacious and untrustworthy and that morality was acquired by imposing the strictest rules of decorum and control. Good action was to be ritually coerced. Xunzi’s teachings encouraged a view of Confucius as a transmitter of ancient norms rather than as a moral exemplar. This realistic strain of Confucianism lends encouragement to Legalism, another philosophy that flourished in China at this time. Legalism, however, demanded strict laws and harsh punishments without hesitation.

State Confucianism

With the Qin dynasty (221–206 BCE), China went from a multi-state arrangement of power based on private and personal loyalties to centralized, bureaucratic rule based on public law. With the changeover from the Qin dynasty to the Han dynasty (206 BCE–220 CE), early Han rulers looked for change from the brutal legalism on which the Qin was based. The first Han emperor (Han Gaozu, reigned 206–195 BCE), a powerful and illiterate wielder of power, had the acuity to ask the Confucian scholar Lu Jia (d. 170 BCE) to discourse on why the Qin failed and Gaozu had succeeded. Lu Jia presented him with twelve lectures (*Xin yu*, or New Discourses), the burden of which was that the Qin ruled with inhumanity and that

Gaozu could enjoy a long rule by observing moral scruples. In 195 BCE, Gaozu paid a ceremonial visit to the grave of Confucius, a symbolic union of brute power and Confucian reasoning. Another Confucian scholar, Jia Yi (201–168? BCE), was asked by the Han emperor Wen (Han Wendi, reigned 179–157 BCE) to propound on the same theme. Jia Yi's efforts (*Xin shu*, or New Writings) brilliantly discussed the faults of the Qin and a vast range of topics on the art of ruling. Thus Confucian ethics and moral behavior entered Chinese politics of state. The grand fusion of moral and political power came when Emperor Wu (or Han Wudi, reigned 140–87 BCE), listening to Dong Zhongshu (179–104 BCE), fully instituted Confucianism as a state religion. Dong's work (*Chunqiu fanlu*, or Luxuriant Dew of the Spring and Autumn Annals) expounded on the role of the scholar in government, whom he claimed was the only appropriate person—not the priest and not the people—to know the ways of heaven, earth, and man. Dong envisaged the ruler, advised by the scholar, as the link between those three realms. He incorporated ancient yin–yang thought (a system based on complementary opposites, as in positive-negative or male-female) into the emerging Han intellectual universe, giving Confucianism properties of a secular religion. The Chinese son of heaven (the emperor), as the first scholar of the land, from then on performed solemn Confucian rites of state. For the next two millennia, by virtue of such institutions as the civil-service examination system, censorial admonition, and imperial universities, the Chinese government fully deserved the adjective *Confucian*.

China after the Han was divided, politically and geographically. The north supported Buddhism, and the Confucian state could only survive in the south, and there only intermittently. China was reunited under the short-lived Sui dynasty (581–618 CE), which favored Buddhism. The Sui, which reunified China in the name of Confucianism, exhibited strong Buddhist features in its ideological outlook. For six hundred years, from the late Han to the Tang dynasty (618–907 CE), Buddhism and Daoism permeated Chinese life. Intellectual, aesthetic, and religious impulses

were greatly stirred by these two outlooks, which competed robustly with Confucianism. In those centuries, these three persuasions together shaped the eventual Chinese cultural outlook: Confucianism supporting a successful public life, Buddhism supporting a religious life of compassion, and Daoism satisfying a psyche freed for imaginative excursions. But in the late ninth century, with the success of the Tang state and government, attention was focused once again on Confucianism.

Neo-Confucianism

Beginning with such late Tang thinkers as Han Yu (d. 824) and Li Ao (d. 844), philosophical attention turned to human nature. Centuries of Buddhist and Daoist influences awakened within Confucianists an interest in the languages of metaphysics and metempsychosis (the movement of the soul after death into a new body). A series of thinkers appeared during the Song dynasty (960–1279) to take up the task of explaining the universe, a task that had hitherto been the province of Buddhism and Daoism. Song thinkers like Zhou Dunyi (1017–1073), Shao Yong (1011–1077), Zhang Zai (1021–1073), the brothers Cheng Yi (1033–1107) and Cheng Hao (1032–1085), Lu Jiuyuan (1139–1193), and finally Zhu Xi (1130–1200) excited their age with intellectual vigor and perspicacity. Two schools emerged in Neo-Confucianism. One, the Cheng-Zhu named for Cheng Yi and Zhu Xi, who did the most for it, saw a phenomenal world of disparate objects and appearances, which they labeled *qi* and a noumenal world of ultimate organizing principles (*li*) behind the *qi*. The other school (*xin*), led by Cheng Hao and Lu Jiuyuan, viewed the universe as a organism, whole in itself, with the organizing principle of *qi* (matter-energy or mind; a different word from the previous *qi*) explaining micro- and macrolevels of human existence. The first school propounded a dualism that explained the seeming disparities between phenomena and their ultimate principles; the latter dispenses with the dualism and offers the mind, or matter-energy, as the means of uniting the knower and the known, thereby stressing human intuitive

Hold faithfulness and sincerity as first principles. • Confucius (551–479 BCE)

faculties. The two schools are known also as the *li* (principle) and *xin* (mind) schools.

Song philosophical efforts imbued Confucianism with metaphysics and a way to explore one's mind and psyche. Buddhist and Daoist influences ebbed, and Neo-Confucianism supported Chinese state and society for the next seven hundred years. Metaphysics and metempsychosis, however, were not the real goal of this Confucian revival, which aimed primarily at appropriating elements of Buddhism and Daoism to buttress its emphasis on human ethics. Using the new dualism, Neo-Confucianism could now point to individual human nature (*qi*) and ideal human nature (*li*), thus exhorting moral action throughout Chinese society toward higher ideals. Chinese society at all levels—whether manifested in village rules or in the imperial civil-service examinations, and in all intellectual endeavors, whether literary composition or historical inquiry—now emulated a Confucian norm. Thus, while Neo-Confucianism was dynamic in the making, it produced subsequent centuries of intellectual, ideological, and pedagogical formalism in China, and its influences were pervasive in Korea, Vietnam, and Japan.

Modern Fate and New Confucianism

As China met the onrush of modern civilization from mid-nineteenth century on, Confucianism came under attack for having supported the entire Chinese body politic and social hierarchy. Intellectuals such as Hu Shi (1891–1962), Chen Duxiu (1879–1942), Wu Yu (1872–1949), and Lu Xun (1881–1936) called for its abolition, chanting “Crush the Confucian Establishment (*Dadao Kongjiadian*)!” and hailing “Science” and “Democracy.” This iconoclasm produced in reaction a twentieth-century neo-traditionalism, nurtured by the call of Zhang Zhidong (1837–1909) in 1898, when China was at the nadir of national strength in face of foreign encroachments, to preserve Chinese culture for substance (*ti*) and exploit Western culture for application (*yong*). While the logic of this saying is faulty in reserving for one culture only morality and for another only instrumentality, it was

eminently satisfying emotionally. Chinese who feared and bewailed the passing of Confucian efficacy embraced the sentiment. Thinkers in the twentieth century such as Liang Soumin (1893–1988) and Xiong Shili (1884–1968) constituted the first generation of the New Confucianism (*Xin rujia*).

After 1950, a second generation of New Confucianists arose in Hong Kong in contradistinction to intellectuals both on the Communist mainland and in Nationalist Taiwan. Amidst manifestos and educational endeavors, scholars such as Tang Junyi, Xu Fuguan, and Mou Zongsan envisaged a new Confucian synthesis combining Confucian moral life with Western modes of living. Their message brought forth a third generation of intellectuals, mostly university professors who wrote in the public sphere from the 1970s. This trend coincided and sometimes coalesced with the rise of an enthusiastic belief that Confucianism was compatible with capitalism. Economic leaps in Korea, Taiwan, Singapore, Hong Kong, and Japan—all nations historically touched by Confucianism—gave them the sobriquet of tigers or dragons of capitalist success. The position was that they were successful capitalist economies *because* of Confucianism. Whether mainland China for two millennia did not develop capitalism *in spite* or *because* of Confucianism has not been satisfactorily answered by the claimants. The bursting of the economic bubble in the late 1990s somewhat shook their faith in this belief.

As modern society's rampant individualism has taken its toll on the collective conscience, New Confucianism has gained adherents who defend its collective ethic against individualism and debate its merits with proponents of individualistic human rights. The debate continues.

Confucius

(551–479 BCE)

CHINESE TEACHER AND PHILOSOPHER

The sayings of Confucius taught millions of Chinese how to lead a good life; they affected Chinese society for more than two millennia as strongly as revealed religions did elsewhere. But Confucius claimed no special knowledge of the supernatural, emphasized everyday human relations, and wished only to preserve ancestral ways. No other civilization relied so completely on merely human authority.

Confucius, or Kongzi as he is known in Chinese, was an itinerant scholar, teacher, and sometime minor official in his home state of Lu during the latter part of the Zhou dynasty (1045–221 BCE), when the Chinese culture area was divided into a large number of competing states.

The very limited success he had as a political and moral reformer in his own lifetime contrasts sharply with the enormous influence his teachings had in future centuries, not only as the philosophical basis for official government doctrine and basic social morality in the unified Chinese Empire after the second century BCE, but also in the surrounding area of Chinese cultural influence, notably in Korea, Vietnam, and Japan.

After the establishment of systematic contact with Europe in the seventeenth century, he became a world figure under the Latinized version of one of his honorific names in China, Kong Fuzi (Kong the Grand Master). Europeans saw in Confucius a distant inspiration and corroboration for the rational humanism of the Enlightenment. More recently, with a new wave of Confucianism carrying the sage to academies, classrooms, and business schools in the West, he has become both an Eastern contributor to global cultural

synthesis and the presumed root cause for the cultural dynamic behind the so-called east Asian economic miracle of the late twentieth century.

Clearly these later reincarnations relate more to Confucianism than to the historical person, but however much they partake of the spirit and historical needs of later times, Confucius, the very human, nonmessianic man of the fifth century BCE, is the starting point.

There is an enormous amount of lore and legend about Confucius's life, but most of it is historically unreliable. The contemporary textual evidence is limited to quotes from the Master and anecdotes about his life that were compiled by his students into a fairly short book, the *Lunyu*, or *Analects*. Less reliably, his thought may also be reflected in a history of his home state of Lu, the *Chunqiu*, or *Spring and Autumn Annals*, which he allegedly authored, and in several early Zhou dynasty (1045–256 BCE) texts which, because of his supposed editorship, became known as the Five (Confucian) Classics.

Certainly these earlier texts, five centuries old in Confucius's time, influenced his thought. He was a self-professed traditionalist, holding up the supposed unity and virtue of the early Zhou dynasty and its de facto founder, the Duke of Zhou, as models for Confucius's own dissolute time of constant interstate warfare and a disintegrating social order. On that point, it is important to note that Confucius came from a social stratum that had fallen from its original position as a warrior aristocracy to become scribe-like functionaries for the increasingly powerful independent states of the later Zhou period. As ritual specialists based on their knowledge of the early Zhou texts, men of Confucius's class preserved and

Highly stylized wood engraving of Confucius. From *The Dragon: Image and Demon*, by Hampden C. DuBose. New York: A. C. Armstrong, 1887.

cultivated the cultural unity of China in a time of political disintegration. For Confucius, *li* (social ritual) was the essential civilizing basis for the social and political order; only through *li* could the individuals realize their basic humanity. The patriarchal nature of the social order embodied in *li* was taken for granted.

In all of this Confucius appears to have been a conservative or even reactionary thinker who wanted to go back to an idealized past in which members of an educated elite had both status and power. But a call to revive the past can be a charge to the present. In some ways, Confucius was a remarkable innovator.

First, there was his emphasis on morality and concern for the welfare of the common people, a theme

further developed by his most famous posthumous disciple, Mencius (or Mengzi, 385–303/302 BCE). Politically, this was expressed in the famous “Mandate of Heaven,” which made the ruler of “all under Heaven”—that is, of a politically unified Chinese culture area—responsible to a nonanthropomorphic supreme deity or cosmic principle (Heaven) for maintaining social harmony through non-selfish virtuous rule. Failure to do so could terminate a ruling house through the people’s exercise of the so-called right of rebellion, further explicated two centuries later by Mencius.

This was Confucius’s first check on tyrannical rule. The second, and ultimately more important, was his emphasis on cultivating knowledge and morality through education. Confucius fundamentally undermined the hereditary principle in a stratified society by taking poor as well as rich students. We can assume that his more impoverished students were the children of good families fallen on hard economic times rather than common peasants, but in the long run this practice of offering a literate, moral education to train people for political leadership laid the social foundation for the political order of imperial China. The ultimate product of such an education was the *junzi*, originally a term for hereditary noblemen, but for Confucius a term that signified an educated, cultivated, and morally centered “noble man.”

Confucius’s teachings, carried on and developed as the Ru school in the centuries after his death, were made the official doctrine of the imperial state during the Han dynasty (206 BCE–220 CE), partly as a backlash against the harsh absolutism of the short-lived Qin dynasty (221–206 BCE). Though much changed in subsequent periods, Confucius’s moral emphasis would form the basis for personal self-cultivation and social harmony in the world’s most enduring political structure and cultural formation—not a bad legacy for a frustrated politician turned teacher.

Congress of Vienna

The Congress of Vienna began in 1814, after Britain, Prussia, Russia, and Austria defeated the Napoleonic Empire and its allies. The series of meetings, meant to stabilize Europe, ended in 1815, with significant European territories under Prussian, Russian, and Austrian control, and control of shipping routes in the hands of the British.

The Congress of Vienna was a series of meetings involving most of the European heads of state held in Vienna, the capital of the Austrian Empire, between September 1814 and 9 June 1815. The purpose of the Congress was to redraw the map of Europe after years of chaos resulting from the Napoleonic and French revolutionary wars (1792–1814). Its proceedings were initially dominated by the four powers of the victorious allied coalition that had defeated Napoleon. Britain was represented by foreign secretary Viscount Castlereagh (Robert Stewart). Prussia was represented by foreign secretary and chancellor Prince Carl von Hardenberg, Russia by Czar Alexander I (1777–1825), and Austria by Prince Klemens von Metternich (1773–1859), who emerged as the architect of the Congress. The defeated French were represented by Charles-Maurice de Talleyrand (1754–1838).

Although Metternich acted as host, there was no formal opening of the Congress, and meetings began in September as delegations arrived. While the major states debated the key issues, delegates from lesser European states dealt with issues such as navigation rights and attended lavish receptions held by the Austrian government. The Congress dissolved after the signing of the Final Act, 9 June 1815.

Preliminaries

With his armies defeated, Napoleon Bonaparte resigned as emperor of France on 11 April 1814 and went into exile on the Mediterranean island of Elba. Allied armies occupied Paris and the prerevolutionary Bourbon dynasty was restored to the throne of France. Louis XVIII (brother of the beheaded Louis XVI) became king, with Talleyrand as foreign secretary. The four allies signed a peace treaty with the new French government on 30 May 1814 known as the First Peace of Paris. Under the terms of the treaty France's borders were rolled back to what they had been in 1792. The final clause in the treaty also specified that all states engaged in the current war should meet in Vienna to resolve outstanding territorial issues.

Territorial Arrangements

Metternich's major objective at the Congress was to ensure that France was surrounded by states strong enough to contain any future French attempts at expansion. Metternich wanted to create a balance of power in Europe that would maintain stability. The Congress of Vienna went on to formalize many territorial arrangements previously agreed upon by the four major allied states. The Kingdom of the Netherlands, which included Belgium and Holland, was created as a strong state on France's northeastern frontier. The Italian state of Piedmont-Sardinia played a similar role on France's southeastern frontier. In central Europe Napoleon's Confederation of the Rhine was abolished and replaced by thirty-nine German states grouped loosely together as the

Jean-Baptiste Isabey, *The Congress of Vienna* (1819). The Congress was convened to redraw the map of Europe after the Napoleonic and French Revolutionary Wars (1792–1814).

German Confederation, with its capital in Frankfurt. The Confederation included German-speaking areas of Prussia and Austria. It also superseded the three-hundred-plus German states that had existed under the auspices of the Holy Roman Empire prior to the French revolution. Prussia was given land on the west and east banks of the Rhine river in order to garrison an army that could march quickly on France in case of an emergency. Austria was meant to have the dominant role in the German Confederation and the Austrians were given presidency of the Confederation. Austria was also to be the dominant power on the Italian peninsula. Austria retained possession of the wealthy northern Italian province of Lombardy and was granted control over the neighboring and equally wealthy province of Venetia. Members of the Austrian royal family, the Habsburgs, were placed on most of the thrones of the remaining Italian states to ensure Austrian dominance and keep the French out.

The Congress recognized British possession of several important overseas territories conquered during the Napoleonic wars. Britain gained the island of Helgoland in the North Sea, Malta in the Mediterranean, the Cape Colony of southern Africa, the

island of Ceylon off India's southern tip, the islands of Mauritius, Seychelles, and Rodriguez in the Indian Ocean, and the islands of Saint Lucia, Trinidad, and Tobago in the Caribbean. Many of these possessions were economically lucrative and gave Britain control over key shipping routes.

The Congress acknowledged the status of Switzerland as an independent and neutral state. Finally, territorial changes were undertaken in Scandinavia. The king of Denmark, too long an ally of Napoleon, lost his possession of Norway to Sweden. Sweden, in turn, was forced to give Finland to Russia.

The Poland–Saxony Dispute

A disagreement over eastern Europe very nearly disrupted the Congress. Alexander I made clear that he wanted to gain control over all of Poland, including Polish provinces previously ruled by Prussia. By way of compensation, the Prussians were to be given the wealthy German kingdom of Saxony. The Austrians and British protested, fearing the growth of Prussian and Russian power in central and eastern Europe. The dispute soon escalated to serious proportions. Talleyrand saw an opportunity to split the victorious

alliance and regain French influence in Europe. He sided with the British and Austrians, and on 3 January 1815, the three powers signed a secret alliance. Each signatory pledged 150,000 troops in the event of war. However, Europe had suffered enough war and a compromise was found. Russia gained most, but not all, of Poland. Prussia gained about 40 percent of Saxony, with the rest remaining independent.

The Final Act and Long-Term Impact

In late February Napoleon escaped from exile and landed in France on 1 March 1815. Napoleon forced Louis XVIII to flee Paris, raised an army, and went to war again with the allies. However this had little impact on the Congress of Vienna. The Final Act was signed on 9 June, and Napoleon was defeated for the last time at the Battle of Waterloo on 18 June 1815.

Most historians agree that the Congress of Vienna created a durable peace in Europe. Although wars broke out among individual European states in the nineteenth century, there was no general war until 1914, a reflection of the fact that no one power left Vienna with unresolved grievances. Britain was arguably the big winner, having won dominance over shipping routes all around the globe, setting the stage for Britain's remarkable imperial expansion in the nineteenth century.

Constantine the Great

(REIGNED 306–337 CE)

ROMAN EMPEROR

In the fourth century Emperor Constantine favored Christianity over paganism in the Roman Empire by adding Christians to his administration, building churches, and raising his heirs as Christians. At the Council of Nicaea (325–326 CE) he defined “orthodoxy” by insisting on standardized beliefs and practices, and thereby pushed Christianity into a monolithic hierarchical autocracy that sanctioned the persecution of nonbelievers.

Though not baptized as a Christian until he lay upon his deathbed, for the bulk of his reign (306–337 CE), Constantine favored Christians. He promoted them into the imperial administration and gave them a variety of tax breaks and financial incentives (all to the disadvantage of members of other religions, notably the pagans); he presided over their Ecumenical Councils and settling doctrinal disputes among them (including the first state-sponsored persecutions of Christian “heretics”); and he restored and built churches (such as the original St. Peter’s in Rome and the Church of the Nativity in Bethlehem, both based on pagan examples such as the great temples of Artemis at Ephesus and Jupiter at Baalbek) that set the style for Christian architecture and iconography for nearly two millennia. But most important, he raised his sons—who reigned after him for another thirty years—as Christians, thus ensuring Christianity’s victory over paganism.

The son of the Western Empire’s ruler, Constantius Chlorus (reigned 305–306 CE), Constantine was acclaimed emperor by the legions in Eboracum (modern York, England) after his father’s sudden death. A series of civil wars ensued, ending with Constantine

in sole control of the empire by 324 CE. In 330 he founded a new—and overtly Christian—capital in the ruined city of Byzantium, renaming it “Constantinopolis” (Constantinople, now Istanbul) after himself, which proved strategically important; in fact, it protected medieval Christendom from Islamic conquest. In 337 on his way to attack the Persians, Constantine died of natural causes at about the age of fifty-two near ancient Nicomedia, and was buried as a Christian in Constantinople.

Though his mother (canonized as St. Helena) had long been a Christian convert, before the Battle of the Milvian Bridge (312 CE) Constantine and many of his soldiers seem to have been devotees of Mithraism, a pagan mystical religion associated with sun worship but holding some doctrinal and ritual similarities to Christianity, including the symbol of the cross. Accounts differ somewhat, but on the eve of battle with his rival Maxentius at the Milvian Bridge, Constantine claims that he saw a cross against a bright sun and the words “In hoc signo vincit” (“By this sign shall you conquer”). Instructing his soldiers to affix this cross symbol to their shields, Constantine won the battle—and the Western Empire.

Somewhat later, under the influence of his mother and her confessor, the Christian bishop Eusebius, Constantine became persuaded that his vision came not from Mithras but from Jesus Christ. The resulting Edict of Milan (313 CE) granted Christianity official toleration and marked the end of the pagan Roman Empire. Though Constantine’s vision has often been seen as a cynical ploy to gain Christian favor, the very small number of Christians in the empire, especially in the western half (about 5 percent of the empire’s overall population was Christian, and most of

Colossus of Constantine. The face of the colossus remains intact, but the rest of the statue is in fragments. Photo by William Vann (EduPic.net).

lived in the eastern half), suggests that the vision and conversion should be seen instead as a bit of clever politicking on the part of the then-persecuted Christians to gain favor, if not ascendancy, in the empire. In this Constantine did not disappoint.

Besides promoting Christians into all levels of the Roman administration, Constantine issued a variety of edicts and orders giving Christians financial rewards and legal immunities not enjoyed by others. He also prohibited gladiatorial games and animal

sacrifices, and in 330 CE, to finance the building of his new capital of Constantinople, ordered the ransacking of the pagan temples of their treasures—bronze doors, gilt idols, and even their gold-shingled roofs—which disastrously affected the pagan cause. He even engaged in the first persecution of non-Christians by Christians. Between this clear favoritism and instructing his children in the new faith, Constantine sent the message that the route to power, influence, and riches now lay through Christianity.

To his horror, Constantine found that rather than a universal monolithic hierarchy, the Christian “church” consisted of mostly independent house-churches loosely confederated with no standardized doctrine, ritual, or scripture. As reported by Eusebius, Constantine considered himself a bishop, a new kind of Christian pontifex maximus, or priest-king, charged with the protection and promotion of Christianity—an example followed by his successors for the next millennium and more. To this end, as soon as he gained control of the whole empire, he called Christian leaders to a council at Nicaea (325–326 CE), where his insistence on standardizing beliefs and practices defined “orthodoxy” and pushed Christianity into a monolithic hierarchical autocracy; his insistence on standardization also led to the first state-sponsored persecution of Christians (the “Donatists”) by Christians, setting yet another dubious example for his successors.

Constantine was both the best and the worst thing that ever happened to Christianity. Without him, Christianity would never have become the critical cultural, political, and religious force that it did, since nowhere has it become a majority religion without state-sponsored favoritism and persecution. Constantine’s insistence on hierarchical autocracy, an orthodoxy of ritual and doctrine, and the persecution

of nonbelievers ensured Christianity’s triumph (and some of its greatest crimes). It also laid the foundation for three critical events in European and world history—the Papal Revolution, the Crusades, and the Protestant Reformation. Without Constantine’s conversion, the modern world as we know it would not exist.

Consumerism

Although the consumption of luxury goods, such as textiles and jewelry, occurred among elites in societies from the earliest times, the spread of consumerism since the eighteenth century is considered a significant development in world history. This fascination with nonessential goods is in part a result of economic growth and prosperity as well as a shift away from nontraditional values.

Consumerism involves a devotion to the acquisition of goods not needed for basic, or even embellished, subsistence. It is further associated with a desire for novelty, even a commitment to faddism, rather than contentment with established styles sanctioned by tradition. The spread of consumerism, socially and geographically, is one of the most significant developments in world history over the past two to three centuries. Growing commitments to consumer culture represent not only a sign of economic change and growing prosperity, but also a significant shift in values.

Beginnings

Consumerism is not, of course, entirely modern. Elites in various societies indulged in aspects of consumerism from the advent of civilization if not before. Bursts of consumerism occurred, for example, at various points in Chinese history, as wealthy landowners and aristocrats built houses with showy furniture and fancy gadgets, and showed off a parade of eye-catching costumes. The passion of Roman elites for Chinese silks was an example of consumerism, and so was the domestic indulgence in jewelry common in wealthy

Muslim homes in the Middle East. As historians increasingly grasp the importance of interregional trade in premodern history, particularly by about 1000 CE, they also detail a growing array of consumer interests. Cotton cloth made in India, for example, with colorful designs, became extremely popular in Japan and other parts of eastern Asia, and ultimately in western Europe. Chinese porcelain gained widespread attention as an export item all around the Indian Ocean (and again, a bit later, in Europe).

There were, however, several constraints on consumerism in traditional societies. One was the poverty of the majority of the population, which precluded significant consumerist commitments. Even elites frequently shied away from full-blown consumerism, particularly in the sense of avid interest in novelty as opposed to established styles. Religious objections often surfaced, and many societies devoted surpluses to glittering religious expenditures more than personal consumerism. Many societies periodically enforced sumptuary laws, which punished displays that were nontraditional or that threatened established social boundaries. Leading consumerists in China were sometimes actually put to death by a government intent on maintaining traditional styles and values. Consumerism, in other words, was not an automatic result of wealth.

Modern Consumerism

Until fairly recently, historians treated consumerism (if they paid any attention at all to what was sometimes seen as a frivolous topic) as a result of industrialization. As output and living standards rose, people were encouraged to use surplus to buy new

Zhou Fang, *Ladies Wearing Flowers* (Tang dynasty). Bursts of consumerism occurred at various points in Chinese history.

goods. While this relationship retains partial validity, major discoveries in the past two decades locate the effective origins of fully modern consumerism in western Europe in the seventeenth and eighteenth centuries. A craze for buying new things and keeping up with the latest fashions spread widely in Western society, affecting urban populations particularly but creeping into the countryside as well—as with domestic manufacturing workers in eighteenth-century Switzerland who defied village customs by indulging in urban-style clothing. Massive markets for secondhand clothing developed, for people who had the consumerist urge but not the money to follow through easily, and thefts of fashionable clothing rose as well. Not only clothing but household furnishings and tableware reflected growing consumerist interests, and there were also some intriguing sidelights, like the frenzy for tulip buying (including paintings of tulips) that swept through Holland in the second quarter of the seventeenth century.

This modern consumerism had three characteristics. First, it was cross-class. While social distinctions were not obliterated, one of the joys of modern consumerism involved buying the same kinds of styles as one's betters—if perhaps of lower quality. Many social critics noted this feature, bemoaning (and exaggerating) the loss of the ability to tell a person's social station by looking at his or her clothes. Consumerism also crossed gender lines. Women were often unduly blamed for frivolous consumerism—men participated heavily as well—but it was true that women found considerable self-expression in consumerism. New interests in tea sets and silverware,

for example, followed from women's new authority to regulate mealtimes in the family, and furniture and clothing often sparked interest.

Second, modern consumerism involved a new apparatus of shops and commercial inducements. Scholars have found the basic elements of consumerist apparatus present in places like Britain in the later eighteenth century. Not only did shops spread, but owners became adept at arranging goods in enticing window displays; they offered loss leaders to lure people in for bargains as a result of which they would also end up buying other goods; they advertised widely, often using aristocrats to testify to the qualities of products like razors or teas. Josiah Wedgwood, a leader in pottery production in eighteenth-century Britain, kept careful track of the shops that sold his goods, experimenting with new styles but with enough market research to learn what ones were catching on, what ones should be pulled back. There were even early signs of consumerist leisure: commercial circuses, for example, began in France in the late seventeenth century (though they had been known earlier in Asia). By the late eighteenth century otherwise traditional rural festivals were beginning to import entertainers from the cities.

Third, modern consumerism acquired new meanings for the people involved. Of course it reflected Europe's growing prosperity (for those with some property—not yet for everyone). It also reflected new levels of international trade. Mass enthusiasm for imported sugar has been labeled the first instance of modern Western consumerism, while the seventeenth- and eighteenth-century interest in tea and

Pendleton's Lithography. Industrialized production of cotton clothing allowed the middle class to indulge in the latest fashions. New York Public Library.

coffee helped support the larger enthusiasm for new tableware. But cultural change was involved as well. For many people, religious focus was declining, and consumerism was an outlet for growing secularism. A more commercial society blurred class lines, while population growth jeopardized established place. Many children, for example, could no longer count on inheriting land or artisanal shops from parents. They might do all right financially—working for wages in domestic manufacturing for instance—but they did not have access to conventional social markers. Consumerism, as a means of showing a new kind of identity and success, could play a crucial role in this context. Growing interest in romantic love, another current of the eighteenth century, also contributed to

the commitment to acquisition, particularly, of course, in personal apparel. Additionally, modern consumerism involved a new desire for personal comfort. The use of umbrellas, for example, provided shelter from bad weather, though some British stalwarts objected to this “unnatural” indulgence as umbrella purchases became common in the eighteenth century. Historians debate the precise mix of factors involved, but they agree that consumerism reflected serious values changes, and not simply the imposition of new lures by greedy shopkeepers.

It is clear, finally, that modern consumerism preceded industrialization in the West, helping in fact to promote it through heightened demand for products like clothing. Growing enthusiasm for cotton cloth, one of the motors of early industrialization, reflected not only its cheapness but also the ability to dye it in bright colors, catching the eye of eager consumerists.

Industrialization and Social Critiques

Consumerism and industrialization combined to promote further changes in commercial apparatus. A cluster of shops in Paris merged in the 1830s to form the world's first department store, and the spread of this kind of outlet marked the further progress of consumerism on a global basis. By the 1860s and 1870s, scientists and popularizers were also noting a brand-new consumerist disease, kleptomania, both in Western Europe and the United States, with middle-class women the most common victims. Here was a sign, if a deviant one, of the kind of personal passion that modern consumerism could entail. Emotional definitions changed. Envy had traditionally been criticized as a debasing emotion, but by the late nineteenth and early twentieth centuries it began to be praised as a motivation for healthy consumerism.

Modern consumerism made many people uncomfortable, which is not surprising given the magnitude of change involved. From the late eighteenth century onward, criticism dogged the phenomenon. Religious authorities objected to secularism—though by the late nineteenth century some mainstream Christian

Small upright player pianos brought musical entertainment to a wider home audience. From *Town & Country*, May 1915.

groups came to terms with consumerism, noting that a good appearance was one of God's blessings. Social critics of course attacked the presumptions of the lower classes and the weaknesses of women. Emile Zola's novel *Germinal* was a long harangue against department stores and women's frailty, which distorted family budgets and led to ruin. Medical authorities might get into the act, noting the bad health effects of too much indulgence (particularly, of course, in food and drink). Socialists sometimes opposed consumerism in the name of purer proletarian tastes; but sometimes they merely insisted that workers be given the means to join in consumerism. Anticonsumerism was also an element in anti-Semitism in Western Europe, with Jews blamed for department stores and other lures to depraved taste. While some of these reactions eased over time—there was less anticonsumerism in the West by the later twentieth century—they remain a factor.

Global Consumerism

Modern consumerism began to spread beyond western Europe during the nineteenth century. The United States followed European fashions in its imports of clothing and food from the 1840s onward, though there had been some signs of consumerist interest earlier. The purchase of watches in rural New York, in the 1820s, has been traced to a desire to copy English fashion, only later leading to an actual interest in keeping more accurate track of time. Department stores spread to major Russian cities by the 1850s, indicating a new upper-class interest in stylish consumerism. Japan's opening to the West involved quick assimilation of many consumer interests. Department stores began to mark the fashionable Ginza district in Tokyo by the 1890s. The same kinds of outlets showed up in Western-influenced Shanghai by the early twentieth century. These geographical extensions of consumerism were not automatic. Asian department stores often mixed traditional displays with Western-style consumerism. They offered concerts and other lures to demonstrate that consumerism was culturally acceptable. Even with this, many locals stayed away, convinced that there was nothing in these outlets that they wanted; and of course there was massive criticism of consumerism not only along the lines already present in the West, but on grounds of its debasing foreignness. As before, the spread of consumerism involved really new values, including an interest in challenging existing social lines and power structures, and the process did not occur overnight.

The spread of consumerism also brought new possibilities for protest. A number of boycotts developed, seeking to use denials of consumerism as a means of attacking foreign intervention or other issues. The Boston Tea Party, before the American Revolution, was a consumerist protest of sorts. By the 1920s Indian nationalists and others frequently used boycotts of foreign products to attack British imperialism, with some success. African Americans employed boycotts in places like Baltimore during the interwar period to protest racial injustice. Boycotts were involved in

A modern-day, multilevel mall.

attacks on apartheid in South Africa in the 1980s. By this point, also, human rights groups frequently spurred boycotts against multinational companies accused of shoddy labor practices in Third World countries. Other kinds of consumer movements in the twentieth century sought protection against fraud and poor quality.

The Twentieth Century and Beyond

Consumerism intensified in the twentieth century. Again, both apparatus and motivation were involved. Advertising became slicker, using new imagery and technology and appealing more deeply to emotion. The first real advertising agency arose in the United States, in the 1870s; the phenomenon spread to Europe during the early twentieth century. Not only growing prosperity but also growing discontent with work promoted new levels of consumerist interest. Many factory workers, bored or nervous on the job, turned to consumer pleasures to compensate. The same pattern could affect middle-class people, increasingly employed in large, faceless bureaucracies and unable to claim traditional satisfactions in personal entrepreneurship.

The new wave of consumerism, from the late nineteenth century onward, fueled by these developments, involved the increasing commercialization of holidays like Christmas. As consumerism globalized, Christmas also became widely popular, even in Muslim societies, for its commercial appeal, while other holidays, like Ramadan, began to include more consumer items like greeting cards.

Global consumerism involved the growing participation of children, surrounded from infancy with store-bought items like teddy bears (named for the American president). Experts began to urge parents to use toys and other consumer items to encourage good behavior. Consumerism also spread widely to the field of leisure, as most mass leisure came to involve purchased pleasures and spectatorship, from sports to movies.

Western leadership in twentieth-century consumerism increasingly involved American initiatives, as the United States became the world's leading consumer society. By the 1990s, however, Japan claimed a share in pioneering consumer fashions, as the sale of "cool" products became the nation's large single export category. A key challenge in consumerism research involves careful comparative analysis (as yet

ill-developed) to recognize common elements in the phenomenon but also key variations, including efforts to establish consumerist patterns different from those in the United States.

By the later twentieth century, also, consumerism increasingly intertwined with a global youth culture. Many young people found participation in consumer fads a means of expressing themselves against parental and other adult control. Again, consumerism had meanings, in terms of power relationships and personal expression, which went beneath the surface. The idea of participating in cosmopolitan styles, and being seen in the process, provided significant incentives for many young people.

The geographical spread of consumerism continued, of course. Soviet Russian society attempted to “co-op” consumerism, with state-run department stores like GUM; but the merger never entirely worked, and consumerist dissatisfaction with communism played a role in the collapse of the system. Urban African participation in consumerism began at least by the 1920s; Chinua Achebe’s novel *No Longer at Ease*, set in 1920s Nigeria, deals with the inroads of consumer culture on traditional family values. Latin American participation increased: by the later twentieth century a trip to Disney World in Florida, complete with shopping spree, was a standard expression of family success and doing right by one’s children. The idea of Christmas shopping spread to Muslim Istanbul, while the purchase of gifts and cards was increasingly added to the religious celebration of Ramadan.

Access to consumerism remained uneven, of course. Many rural areas in Asia and Africa were barely touched, and this fact added to the increasingly important rural–urban divide in countries like China. Outright resistance continued as well. The rise of religious fundamentalisms from the 1970s onward represented in part a protest against consumerist values, including their frequent association with sensuality and sexual license. Many

post-communist Russians resented consumerist displays by the “new Russian” middle class, partly, of course, from envy but partly from an older belief that community sharing should take precedence over individual expression. The process of assimilating consumerism has continued into the early twenty-first century.

Containment

The term *containment* is used most often in an historical context to describe the United States' policy toward the spread of USSR influence during the latter half of the twentieth century. The policy led to U.S. involvement in the Cold War, which included armed conflicts in Korea and Vietnam.

A policy aimed at containing, or restricting, a hostile or potentially hostile power through use of diplomacy and possibly force is referred to as *containment*. Historical examples of containment include the coalitions designed to contain French power in Europe during the eighteenth and early nineteenth centuries, or Chinese attempts to contain Vietnamese and Soviet influence in Southeast Asia after 1975. Containment can also be seen in the actions of Britain on the eve of World War II. During the mid-to-late 1930s the British government pursued a diplomatic strategy known as appeasement in dealing with Nazi Germany. However Hitler proved unappeasable and uninterested in long-term peaceful solutions. The Nazi occupation of Czechoslovakia on 15 March 1939 meant the end of appeasement. Instead the British resorted to containment by issuing a series of territorial guarantees to countries in Eastern Europe, most notably Poland. According to the guarantee, should Poland find itself attacked by Germany, Britain would come to its defense. In this manner, the British were attempting to contain German power in Europe. The Germans attacked Poland on 1 September 1939 and Britain declared war on Germany two days later. The term "containment" has many historical examples but is usually associated with the policy followed by the United States toward the USSR during the Cold War.

Origins of Cold War Containment

The months immediately following the end of the World War II saw deterioration in relations between the Western powers and the Soviet Union, who had formerly been allies in the war against the Axis states. British and American statesmen watched in alarm as the Soviets solidified their control over Eastern Europe. The Soviets seemed to be threatening Turkey and Iran, while a Communist insurgency in Greece steadily gained force. The Americans and British also blamed the Soviets for the slow pace of talks over the future of occupied Germany. An atmosphere of mistrust and unease settled over East–West relations.

George Kennan and Containment

On 22 February 1946, George Kennan (1904–2005), a staff member of the American embassy in Moscow, and longtime Soviet expert, sent a document analyzing Soviet policy to his superiors in Moscow. Kennan's analysis became known as the "Long Telegram," and was published in 1947 in the influential American journal *Foreign Affairs*. The journal editors attributed the article to "Mr. X," even though it was generally known that "Mr. X" was actually George Kennan. Kennan's analysis of Soviet foreign policy found widespread support in Washington and soon became the theoretical basis of containment.

Kennan believed that the USSR, for ideological and historic reasons, was an inherently expansionist power. In order to justify their tyranny, Kennan argued, the Soviet leaders had to convince their people that the USSR was threatened by hostile capitalist powers. The Soviets would seek to expand territorially

because that had been the pattern of Russian history. Surrounded by hostile nomadic tribes, living on an open, vulnerable plain, Russian rulers had found security in conquest. As well, Communist ideology demanded that workers in foreign countries be “liberated.” Kennan noted that if the Soviets were confronted at one point they would simply retreat and seek to expand somewhere else. Kennan thought that the Soviets could not be trusted in negotiations. They might agree to tactical concessions but would never give up on their historic mission. However, Kennan did not believe that the Soviets wanted war, since they took a long-term view and were content to wait for historical trends to play themselves out. Since the collapse of capitalism was inevitable, according to Communist theory, there was no need to take dangerous risks. Kennan recommended that the United States pursue “a policy of firm containment, designed to confront the Russians with unalterable counter-force at every point where they show signs of encroaching upon the interests of a peaceful and stable world” (Kennan 1947, 581). Kennan speculated that if the USSR were unable to expand then long-term internal pressures would force drastic changes in the Soviet system.

Critics of Containment

Kennan’s views, although popular in the government, provoked some criticism when made public. Walter Lippmann, a popular syndicated newspaper columnist and foreign affairs commentator of the time, wrote that containment would involve the United States in numerous conflicts around the globe. The resources of the United States would be overextended and worn down. Others on the political left criticized containment on the grounds that they opposed any confrontation with the USSR. Henry Wallace, a member of Truman’s cabinet and a former vice president under Roosevelt, publicly broke with Truman and said that Soviet policy was driven not by expansionism but rather by fear. Containment would only worsen the situation. In 1948 Wallace ran against Truman in the presidential election, but finished a poor fourth.

Containment Strategies

Kennan’s views provided the basis for many American policies toward the USSR in the years to come. Early in 1947 the British government informed Washington that it would be unable to continue aid to the government of Greece, which was then fighting a bitter civil war against the Greek Communists. Since it was assumed that the Soviets were supporting the Greek Communists, Washington feared that the fall of the Greek government would bring Soviet power to the shores of the Mediterranean. On 12 March 1947, President Harry Truman, in a bid to gain Congressional support for a \$400 million aid package to Greece and Turkey, proclaimed what has come to be known as the Truman Doctrine. Truman said that he believed that “it must be the policy of the United States to support free peoples who are resisting attempted subjugation by armed minorities or by outside pressures. I believe that we must assist free peoples to work out their own destinies in their own way” (Dunbabin 1994, 83). Truman added that American help should focus on economic and financial aid.

At the same time concern in Washington over the growth and popularity of West European Communist parties led to the conclusion that a slow economic recovery from the war was contributing to the appeal of the Communists. Accordingly on 5 June 1947, United States secretary of state George Marshall announced a program of extensive economic aid to European states in need. Formally known as the European Recovery Plan, it is more popularly remembered as the Marshall Plan. The USSR and its satellite states refused to participate, stating that they were not about to open their economies and societies to U.S. trade and U.S. auditors. Over the next four years most Western European states requested Marshall Plan assistance, with totals reaching more than \$17 billion. The Marshall Plan was fundamental to the West European economic recovery of the postwar era, although Communist parties in France and Italy remained popular for many years.

Although Kennan had emphasized nonmilitary economic and diplomatic strategies for containment,

and had participated in the drawing up of the Marshall Plan, the intensification of the Cold War meant that military containment came to the fore. In August 1949 the USSR successfully tested an atomic bomb, breaking the United States monopoly on atomic weapons. In October 1949 the Chinese Communists, led by Mao Zedong, came to power in China. Finally, on 25 June 1950 the armies of Communist North Korea invaded South Korea. Although South Korea had never previously been seen as vital to United States strategic interests, Truman decided that he could not stand by. The United States entered the war on the side of the South Koreans and soon became bogged down in a bloody three-year stalemate.

Earlier in 1950 the United States government had undertaken a comprehensive review of its global defense strategies. The review, completed by September, was obviously influenced by the events of 1949 and the Korean War. Known as NSG-68, the review recommended a massive buildup of American atomic and conventional defense forces. The document almost certainly marked a turn toward a military emphasis in containment. Kennan later protested that by “counter force” he had meant more than just military force, but such distinctions were quickly lost in the heated atmosphere of the Cold War.

Truman did not run in the 1952 presidential election, which was won by Republican Dwight D. Eisenhower. During the campaign the Republicans bitterly criticized containment for abandoning the people of Eastern Europe to a tyrannical political system. John Foster Dulles, soon to be Eisenhower’s secretary of state, promised to “roll back” Soviet influence in Eastern Europe. But Dulles recoiled from the idea of war, and so could do little more than continue containment after 1952. Dulles knew that a direct attempt to intervene in the Soviet Eastern bloc would provoke full-scale war. Instead, Dulles assumed, especially after Stalin died in 1953, that forces of nationalism in Eastern Europe would do the job in bringing down the Soviet system. Yet another review of American defense strategy, carried out in 1953, came to the same conclusion. However, the Americans did escalate the propaganda war by improving the broadcast capabilities of Radio Free Europe.

Containment after Korea

The Korean War also posed continuing serious questions about what exactly containment meant. Was the United States to become involved in every single conflict around the globe where Communism was perceived to be a threat? Were some areas of the globe more valuable to the United States than others? Some commentators, such as Henry Kissinger, have pointed out that containment was essentially a defensive, reactive policy that conceded the initiative to the other side. Others have argued that proponents of containment grossly overrated the Soviet military threat, which in the early 1950s was still minimal in terms of atomic weapons. Containment was also said to have underestimated the usefulness of long-term negotiations in solving East-West problems.

During the 1950s supporters of containment conjured up the metaphor of a row of dominoes to illustrate what might happen if containment failed in any given area. The successful toppling of the first domino means the whole row will fall. A successful Communist takeover in any one country might prompt a whole series of takeovers, resulting in an eventual direct threat to the United States itself. The logic of containment resulted at least partially in American involvement in the Vietnam War in the early 1960s. Some feared that the loss of South Vietnam would topple other Southeast Asian states, so the United States became involved in a second major land war in Asia since 1945. The result was a costly and bitter conflict, deep social division in the United States, and the eventual military defeat of South Vietnam in 1975.

With military containment discredited, U.S. presidents still had to struggle with how to respond to perceived Soviet gains in what was seen as the zero-sum nature of the Cold War. In Angola and southern Africa in the late 1970s, and in Afghanistan and Central America in the 1980s, Washington relied on proxy forces to combat Soviet influence. The United States found dissident groups and organizations opposed to Soviet-backed Marxist states. Such organizations were then armed and supported by the U.S. Examples include the Contra rebels in Nicaragua, the

mujahideen resistance factions in Afghanistan, and the UNITA movement in Angola.

The obvious decline of the USSR in the late 1980s prompted much retrospection on Kennan's original ideas and the ways in which they had been used, or misused. In 1987 *Foreign Affairs* reprinted Kennan's article in its entirety. Some saw Kennan as a far-sighted and perceptive observer of the USSR, while others decried what they felt was the distortion of his ideas and the high cost of military containment over the years.

Historically containment, in the context of the Cold War, will be remembered as a doctrine that did much to define the 'battle lines' of the Cold War. The wars fought under the banner of containment had a tremendous impact of the peoples of Asia and Africa. However, containment will also remain an important diplomatic tool in the new century and in the near future will most likely be applied to perceived 'rogue' states.

Corporations, Multinational

Trading companies in the 1600s, precursors to multinational corporations (MNCs), acquired and controlled foreign assets in order to reduce costs and risks and to gain advantage over their competitors. Modern MNCs that invest directly in foreign markets benefit from advances in research and development, from privileged access to capital and finance in the home country, and from the ability to manage organizational, marketing, and branding techniques.

Multinational corporations (MNCs) are corporations that own an asset in more than one country. We can classify multinational corporations according to their function. For example, market-oriented overseas multinational corporations are those that invest abroad to sell their products directly in foreign markets; supply-oriented multinationals are those that operate abroad to have access to or control over strategic input for their production process.

Many multinational corporations are both market oriented and supply oriented. The best examples are those companies that are involved in oil discovery, refining, and distribution through an international network in a world market. According to another taxonomy (system of classification), a multinational corporation can be vertically integrated, horizontally integrated, or diversified, according to the nature of its foreign assets. Moreover, the production facility located in the host country must be not only owned but also controlled: CalPERS (California Public Employees Retirement System), one the most important pension funds in the world, is *not* a multinational corporation. It is, in fact, a major shareholder in many countries' largest corporations but does not

exert control over their management. The conjunction of foreign ownership and a certain degree of control over the overseas subsidiary creates the concept of foreign direct investment (FDI). FDI can take the form of the acquisition of an existing facility or of the realization of a completely new production unit (greenfield investment). When FDI is less than 100 percent of the subsidiary's capital, different taxonomies of MNC can be used. The most common such MNC is the joint venture, which often involves two or more partners, not necessarily all foreign firms. For instance, in many cases the only way for a nondomestic firm to establish a production facility in a country is to associate itself with a local firm, creating a new venture.

Patterns of Evolution

According to the preceding definitions the MNC is a quite old phenomenon, dating back at least to the "commercial revolution" of the Middle Ages and the following emergence of large colonial empires at the beginning of the modern period. Single merchants and bankers started quite early to conduct overseas activities, and soon national trading companies were investing abroad. Examples are the British East India Company, the Compagnie Generale de Belgique (General Company of Belgium), and the Vereenigde Oost-Indische Compagnie (Dutch East India Company), which, although based in Europe, owned, managed, and controlled production assets in east Asia, India, and Africa. With the first industrial revolution the rate of diffusion of multinational activity began to increase. High transportation costs; uncertainty; high custom tariffs or, alternatively,

Samchuk-Suphanburi, Thailand. Coca-Cola®, one of the world's largest corporations, has come a long way from its humble beginnings in Atlanta, Georgia, in 1886.

incentives and a favorable attitude shown by a host country; or simply a competitive advantage led to a spin-off of production investments from the most advanced European nations. This is, for instance, the case of Swiss entrepreneurs in the cotton industry who invested during the mid-nineteenth century in northern Italy, a promising market that also provided a cheap and docile workforce.

The first wave of globalization during the second half of the nineteenth century brought an extreme form of the MNC: the free-standing company (FSC). In its simplest form the FSC was a company that raised resources in home capital markets and invested them exclusively abroad in production facilities. The FSC was, according to many scholars, the most relevant form of British foreign investment at the eve of the twentieth century. The combination of

two phenomena—the technological progress in transportation and communications and the diffusion of scale-intensive, large corporations—has further diffused FDI. The second Industrial Revolution created a growth in the absolute amount of FDI (which on the eve of World War I was \$40–50 billion). At the same time leadership in multinational activity began to be transferred from the United Kingdom to the new world economic leader, the United States. The leading position of the United States was further confirmed after World War II and during the 1960s when U.S. conglomerates began an extensive policy of acquiring foreign companies. During the same period and after the 1980s other countries, mainly in Europe (France, Germany, the United Kingdom, and the Netherlands) and Asia (Japan), began to increasingly challenge U.S. leadership in FDIs. At the beginning of the new millennium, when the recently industrialized countries of east Asia began consistent multinational activity, the world stock of outward FDI exceeded \$2 trillion.

Theories

Scholars have offered various theories to explain the existence of multinational corporations. Economic imperialism theorists (going back to the Russian Communist leader Vladimir Lenin) saw the MNC simply as an instrument for the diffusion of the new capitalist order on a world scale. According to other theorists, such as the economist Raymond Vernon, we must see the MNC as the natural evolution of the life cycle of a product; in this model FDI is directly connected to the maturity and standardization of a product. When producing a product at the lowest marginal cost is vital, a corporation will tend to transfer the production abroad, especially in developing economies.

Since the 1960s, however, starting with the writings of the U.S. scholar Stephen Hymer, the analysis of multinational corporations has progressed. Scholars have identified a number of factors that justify the advantage that a MNC gains by investing directly in foreign markets (instead of simply exporting). Among such factors scholars have given special importance

to proprietary technology and research and development; privileged access to capital and finance in the home country; and the ability to manage organizational, marketing, and branding techniques, given the competence acquired in the home market. A long experience in multinational activity has been considered a competitive advantage in itself. In other cases FDI flows are influenced by the institutional context in the host country in terms of trade and industrialization policies.

The relationship between multinational activity and uncertainty is the core of other theories that try to explain the existence of multinational corporations from a neoinstitutional perspective. This is, for instance, the case of transaction costs (TC) theory, which tends to consider the imperfections in world markets, especially for raw materials and other intermediate products, as a major force driving the internalization of overseas activity of a corporation. The British scholar John Dunning formulated a more general approach at the beginning of the 1990s. In his approach (the so-called OLI paradigm) the MNC is an organization that is able to understand and manage a complex array of variables in noneconomic fields, such as politics or culture in the host country. The decision to invest abroad is the outcome of a series of advantages the corporation has, or gains from the investment, in terms of (O) ownership (e.g., of superior technologies or management, or marketing techniques), (L) location (e.g., in terms of resource

endowment of the host country), (I) internalization of segments of the value chain (e.g., in some cases it is better to control directly the distribution in a foreign market than relying on local agents).

Cosmology

The human understanding of the universe has dramatically changed over time, with advances made in extrapolating evidence from carefully observed phenomena, and with discoveries in disciplines such as particle physics. Each change in the cosmological model has diminished human significance in a vast and ancient universe.

Cosmology is the study of the universe as a whole, its structure, composition, history, and probable future. Because human records only extend over a tiny fraction of the lifetime of the universe and human exploration has been restricted to a very small region, cosmologists are forced to rely on extrapolations and speculation beyond what would be acceptable in the other sciences. While much of cosmological theory has no immediate relevance to understanding the environment of living organisms on earth, cosmology sheds light on the time scale of biological evolution and the possibility of new resources being discovered. Cosmology touches at several points on issues also of concern to religion and has for many thinkers required a revision of their estimate of the place of humans in nature.

The Geocentric Universe and Astrology

As ancient humans watched the daily transit of the sky by the sun, moon, and stars, it was only natural to assume that the Earth was the center about which these celestial bodies moved. On closer observation it became apparent that a few star-like objects moved a bit differently, seeming to wander against the

background of stars that traveled together across the sky as if attached to a transparent sphere. The movements of the wanderers, called planets, was thought to influence human affairs and a group of professional astrologers began to predict the future for individual clients by casting horoscopes, based on the position of the planets at the time of their births. Tables of planetary positions were worked out, assuming the planets moved in circular orbits about the earth. The most famous of these, the *Almagest* of Ptolemy (90–168 CE) is the basis for astrological tables used today.

A Heliocentric Universe

The Ptolemaic model held sway until the Polish clergyman Nicolas Copernicus (1473–1543) published *On the Revolutions of the Celestial Orbs* in 1512. Realizing that his views would meet with disapproval by church authorities, he postponed publication of his book until his dying year. The Italian mathematician Galileo Galilei (1564–1642) popularized the Copernican model and incurred censure for his views. In actuality, though, both the Ptolemaic and Copernican systems were defective in assuming, on philosophical grounds, that planetary motion must be circular. Based on the careful observations of the Danish nobleman Tycho Brahe (1546–1601), the German scholar Johannes Kepler (1571–1630) demonstrated that the planets moved about the sun in elliptical orbits. It remained for the great English mathematician Sir Isaac Newton (1642–1727) to discover the laws of motion and of universal gravitation that explained the elliptical orbits and confirmed the heliocentric model.

Aristotelian Cosmos, based on the theories of Ptolemy. From Peter Apian, *Cosmographia* (1524).

A Very Large and Old Universe

By the beginning of the twentieth century, astronomers were in general agreement that the sun was just one of many stars and that the visible stars in the sky were clusters together in a large structure, the Milky Way galaxy. A group of indistinct fuzzy objects called nebulae had yet to be explained. In 1918, the American astronomer Harlow Shapley (1875–1972) was able to demonstrate that the sun was quite far removed from the center of the Milky Way. In 1923 the American astronomer Edwin Hubble measured the distance to the Andromeda nebula, showing that it and the other nebulae were actually galaxies in their own right. The universe was understood then to consist of many galaxies like our own and thus to be very much larger than anyone had previously expected.

A theoretical result known as Olber's paradox implies that the universe, or at least the stars in it, could not be of infinite age, since, if it were, the sky would be as bright at night as during the day. In 1929 Edwin Hubble, working with the world's then largest telescope, on Mount Palomar in California, was able to demonstrate that galaxies far from the Earth were moving away from it with a velocity that increased

with distance. This fact along, with other evidence, lead to the conclusion that the universe we know, was at its beginning, some ten to twenty billion years ago, confined to a very small region of space and began to separate as the result of a giant explosion, the "big bang."

Life Cycles of Stars and the Origin of Chemical Elements

Until the twentieth century the energy source of the sun was a mystery. In the 1930s it was discovered that the fusion of small nuclei to form a large nuclei would result in the transformation of a small fraction of the smaller nuclei's mass into heat energy according to Einstein's famous formula, $E=mc^2$. It is now known that the power source of the sun is the fusion of hydrogen nuclei to form helium nuclei. Computer modeling now shows that after the sun, which is now about five billion years old, has transformed most of its hydrogen into helium, its inner regions will contract and become hotter until the combining of helium nuclei to form carbon and oxygen nuclei becomes feasible. After that further contractions will occur until atoms as heavy as iron will be formed. The formation of nuclei heavier than iron occurs, either by a slow process in which a heavy nucleus absorbs neutrons that are then converted to protons through beta decay, or when massive stars explode as supernovas.

Our current understanding of the distribution of chemical elements is as follows: hydrogen and a certain amount of helium were formed during the big bang, about 13 billion years ago. The basic elements of life and those found in large quantities on earth had to be formed in stars that had passed the hydrogen burning stage and ultimately returned their substance to the interstellar medium where it could condense as a new star, the sun, and planets formed. Elements with atomic numbers higher than iron are formed in very old stars or in supernova explosions, and therefore are destined to remain rare regardless of how thoroughly the mineral resources of Earth are explored.

A board game “simulates” a voyage through the universe based on the research of the Danish astronomer Tycho Brahe. Engraving by Estienne Vouillemont, 1661. From *Le Noble jeu de l'oie en France, de 1640 á 1950*. (Paris: Gründ, 1950).

Cosmology Today

Modern cosmologists apply the principles of relativity theory and the discoveries arising from experiments in particle physics to try to understand the origin and the ultimate fate of the universe as we know it. They also must assimilate observations from the Hubble telescope and a number of artificial satellites that show the universe to be relatively uniform when averaged over large distances. In contrast to the assumption that the Earth held a privileged position in the universe, most cosmologists today make assumptions of isotropy and homogeneity, that is, that the universe looks pretty much the same from

any point in it and in any direction in space. Perhaps the biggest questions in cosmology today are the reason for this uniformity, which has been taken as evidence for a period of especially rapid expansion or inflation shortly after the big bang, and the nature of the so-called dark matter that is needed to explain the rotational speeds of galaxies as observed. Once these questions are resolved, cosmologists will have a better understanding of the early history of the universe and may speak with greater confidence about its distant future.

Creation Myths

Almost every human society has had a set of stories that explain the origins of the cosmos; these creation stories (never “myths” to those who believe them) attempt to give meaning to all of existence and often reflect the cultures from which they derive. Modern creation stories, although based on scientific observation and research, still strive to answer the same basic questions as earlier myths.

Creation myths are stories, or collections of stories, that tell of the origins of all things: of communities and landscapes, of the Earth, its animals and plants, of the stars, and of everything that exists. They represent what “history” has meant for most human communities. Creation myths appear to have existed in all human societies and they are deeply embedded within all the major world religions. By offering answers to questions about origins, creation myths provide maps of reality within which people can learn about their place in the cosmos and the roles they are expected to play. As Barbara Sproul states in her book *Primal Myths* (1991, 2–3): “[C]reation myths are the most comprehensive of mythic statements, addressing themselves to the widest range of questions of meaning, but they are also the most profound. They deal with first causes, the essences of what their cultures perceive reality to be. In them people set forth their primary understanding of man and the world, time and space.” Marie-Louise von Franz, in *Creation Myths* (1972, 5), writes that they “refer to the most basic problems of human life, for they are concerned with the ultimate meaning, not only of *our* existence, but of the existence of the whole cosmos.”

Many striking parallels exist between traditional creation myths and the foundation stories of modern societies, which are embedded within modern science and historiography. Are modern accounts of origins fundamentally different from those of traditional societies? Or can they, too, be regarded as “creation myths”? Such questions are worth pursuing because they raise important questions about the nature of the truths that can be attained within modern historiography, particularly when, like world history, it aspires to a coherent account of the past on many scales.

A Creation Myth Example

Creation myths have taken many different forms. The Genesis story within the Judeo-Christian-Islamic religious tradition counts as a creation myth. So do the origin stories found in the oral traditions of societies without written histories. Appreciating the full significance of creation myths is difficult because, like so many cultural traits, their meaning is obvious to those brought up with them, but opaque to outsiders. So the creation myths of others are almost invariably experienced as strange, exotic, and *wrong*. As the definition of “myth” in the *Encyclopaedia Americana* points out, “a myth is understood in its own society as a true story. (It is only when it is seen from outside its society that it has come to acquire the popular meaning of a story that is untrue)” (Long 1996, 699). The difficulties of understanding a creation myth from outside can be appreciated from the following extract. It comes from the account of a French anthropologist, Marcel Griaule, who is summarizing his conversations with Ogotemmeli, a wise man of the Dogon people of Mali. Ogotemmeli had been authorized to

This diagram, combining myth and reality, depicts an eleventh-century African Muslim belief about the origin of the Nile.

reveal something of his society's cosmology, but it is clear from the conversation that he was aware of speaking to an outsider, who might not understand or fully appreciate all he said, and Griaule himself was acutely aware of the difficulties of this complex process of translation.

The stars came from pellets of earth flung out into space by the God Amma, the one God. He had created the sun and the moon by a more complicated process, which was not the first known to man but is the first attested invention of God: the art of pottery. The sun is, in a sense, a pot raised once for all to white heat and surrounded by a spiral of red copper with eight turns. The moon is in the same shape, but its copper is white. Ogotemmeli said he would explain later the movements of these bodies. For the moment he was concerned only to indicate the main lines of the design, and from that to pass to its actors. He was anxious . . . to give an idea of the size of the sun. "Some," he said, "think it is as large as this

encampment, which would mean thirty cubits. But it is really bigger. Its surface area is bigger than the whole of Sanga Canton." And after some hesitation he added: "It is perhaps even bigger than that." . . .

The moon's function was not important, and he would speak of it later. He said however that, while Africans were creatures of light emanating from the fullness of the sun, Europeans were creatures of the moonlight: hence their immature appearance. . . .

The god Amma . . . took a lump of clay, squeezed it in his hand and flung it from him, as he had done with the stars. The clay spread and fell on the north, which is the top, and from there stretched out to the south, which is the bottom of the world, although the whole movement was horizontal. The earth lies flat, but the north is at the top. It extends east and west with separate members like a foetus in the womb. It is a body, that is to say, a thing with members branching out from a central mass. This body, lying flat, face upwards, in a line from north to south, is feminine. Its sexual organ is an anthill, and its clitoris a termite hill. Amma, being lonely and desirous of intercourse with this creature, approached it. That was the first occasion of the first breach of the order of the universe.

Ogotemmeli ceased speaking. . . . He had reached the point of the origin of troubles and of the primordial blunder of God. "If they overheard me, I should be fined an ox!"

At God's approach the termite hill rose up, barring the passage and displaying its masculinity. It was as strong as the organ of the stranger, and intercourse could not take place. But God is all-powerful. He cut down the termite hill, and had intercourse with the excised earth. But the original incident was destined to affect the course of things for ever; from this defective union there was born, instead of the intended twins, a single being, the *Thos aureus* or jackal, symbol of the difficulties of God. . . . God had further intercourse with his earth-wife, and this time without mishaps of any kind, the excision of the offending member having removed the cause of the former disorder. Water, which is the divine seed, was thus able to enter the womb of the earth and the normal reproductive cycle resulted in the birth of twins. Two beings were thus formed. God created them like water. They were green in color, half human beings

and half serpents. From the head to the loins they were human: below that they were serpents. Their red eyes were wide open like human eyes, and their tongues were forked like the tongues of reptiles. Their arms were flexible and without joints. Their bodies were green and sleek all over, shining like the surface of water, and covered with short green hairs, a presage of vegetation and germination. These figures were the Nummo twins, water gods who later play a crucial role in the creation of the earth. (Sproul 1991, 50–51, citing Griaule 1975, 16–40)

Features of Creation Myths

These brief extracts, from the start of a long and complex story, illustrate several features of creation myths in general. First, Ogotemmel's account is told as a story. This may be simply because narrative is the most powerful and memorable way of explaining and transmitting complex, important truths. "Like myth, memory requires a radical simplification of its subject matter. All recollections are told from a standpoint

in the present. In telling, they need to make sense of the past. That demands a selecting, ordering, and simplifying, a construction of coherent narrative whose logic works to draw the life story towards the fable" (Samuel and Thompson 1990, 8).

Second, origins are explained as the result of conscious actions by spirits or gods. That spiritual entities created the basic structures of the world is a default hypothesis in many traditional cosmologies. But it is not universal. Many origin stories rely on metaphors of birth, positing the existence of a primordial egg or a primordial sexual act, whose meaning can be understood more or less literally. Some origin stories explain creation as an awakening from sleep, a reminder that our own personal origin stories all have the quality of awakening from preconsciousness. Some creation myths face the paradoxes of origins squarely, positing a realm preceding that of the gods, which was balanced precariously between existence and nonexistence. According to the Rig Veda, the ancient sacred hymns of northern India, "There was

The central part of a floor mosaic (c. 200–250 CE) from a Roman villa depicts Aion, god of eternity, and the Earth mother Tellus (the Roman equivalent of Gaia). The children might possibly personify the four seasons.

neither non-existence nor existence then; there was neither the realm of space nor the sky which is beyond. What stirred? Where? In whose protection? Was there water, bottomlessly deep? There was neither death nor immortality then. There was no distinguishing sign of night nor of day. That one breathed, windless, by its own impulse" (O'Flaherty 1981, 25). Such language hints at the paradox present in all stories of ultimate origins—how can something (whether a god or an entire universe) come out of nothing?

Third, all creation myths are more complex than they may seem at first sight. Because they deal with ultimate realities, with truths so complex that they can only be referred to using richly metaphorical or poetic language, their tellers are usually well aware of their paradoxical, even provisional nature. At one point, Marcel Griaule was puzzled by a detail in Ogotemmeli's story, according to which large numbers of creatures appeared to be standing on a single step, only one cubit deep and one cubit high. How was that possible? Ogotemmeli replied: "All this had to be said in words, but everything on the steps is

a symbol, symbolic antelopes, symbolic vultures, symbolic hyenas. Any number of symbols could find room on a one-cubit step." Griaule adds that the word Ogotemmeli used for symbol literally meant "word of this (lower) world" (Sproul 1991, 64).

Fourth, embedded within cycles of creation myths there is generally much hard empirical information about the real world, information about animal migrations, about technologies of hunting and farming, information that younger members of society needed to learn. Such information is often of little interest to outsiders, who may thereby miss the practical, empirical nature of most cycles of myth, but it helps explain their fundamental role in informal systems of education. Ogotemmeli's story, for example, contains a long list of important animals, much lore about procreation and sexuality, details of the major grains farmed in his region, and symbolic accounts of human anatomy and the world's geography.

Finally, partly because they contain so much familiar information, creation stories have the feeling of truth for insiders, just as modern science does

Page from the Translation of the Entire Text of the "Yao Annals of Creation," a bilingual document recording the origins of the Naxi peoples living near the Li River in Yunnan, China. The Dongba glyphs (top) characters were developed circa the seventh century; here they vividly portray the story of Chaozeng Lien, the founder of the Naxi, and his wife, Chenhong Baobai. National Library of China.

for those educated in the early twenty-first century. To those brought up with them, particular creation myths represent the best available guide to reality and much of what they say fits in well with commonsense experience. This does not mean that creation stories are necessarily treated uncritically by insiders—it is always possible to argue about details of a creation story or express skepticism or even confusion about certain aspects of the story. As Griaule comments of Ogotemmeli, “Ogotemmeli had no very clear idea of what happened in Heaven after the transformation of the eight ancestors into Nummo” (Sproul 1991, 59). But it does mean that familiar creation myths are felt to be the best available guides to reality and therefore to conduct; in some sense, they hold society together. And this makes them extremely important, not to be told lightly or carelessly, and to be treasured and passed on with care by those who keep the knowledge they contain. Creation myths contain potent information, which is why Ogotemmeli lowers his voice when discussing the first blunder of the God Amma.

Similarities and Differences

This partial list of the features of traditional creation stories suggests some of the main similarities and differences between creation myths and modern, “scientific,” accounts of the past. Both modern and traditional accounts of origins play an important educational role because traditional creation stories also contain much carefully tested information about the real world. Like creation myths, modern accounts of the past can also be passed on best in narrative form, which is still the dominant form for history writing and much popular science. Modern accounts of origins also struggle with the problem of ultimate origins, something that is clear in the case of modern big bang cosmology, which can say nothing precise until just after the moment of creation. Indeed, like many traditional creation myths, modern physics sees non-being (the vacuum) as a state of potentiality, a realm of emptiness out of which things can appear. Further, when the epistemological going gets tough, even modern science has to fall back on complex and

paradoxical concepts whose full significance may remain somewhat obscure. In this sense, concepts such as gravity or black holes or quantum uncertainty play roles similar to those of gods or other mythic creatures in traditional creation stories. Finally, to an educated person today, modern origin stories have the same feeling of truth that traditional creation myths had for those brought up within them. Because of these many similarities, it seems reasonable to suggest that modern “scientific” historiography, particularly in the form of world history, can play many of the roles that creation myths played in the past.

Yet there are also important differences. It is tempting to claim that modern scientific accounts of the past are truer than those of traditional creation stories. Such claims may be true, but they need to be made with care. Even modern origin stories are anchored in time and place, so in the future they will undoubtedly seem naive and primitive in some respects, as traditional creation stories do today. Furthermore, all creation stories have something to teach outsiders insofar as they offer different ways of thinking about reality. For example, many environmentalists have argued that modern societies need to recapture the sense of being a part of the natural world that is so pervasive in the creation stories of foraging societies. A clearer difference is that scientific origin stories (like modern science in general) aim at universality. They expect to be believed not by just a single culture, but by all educated people on Earth. To earn such universal respect, they require a flexibility and openness that was lacking in many creation stories, for they have to appeal to intelligent people from many different cultural backgrounds, and they have to be able to incorporate new information. This requires a constant testing of hypotheses and details to avoid the parochialism of most traditional creation myths. Because modern scientific historiography (like science in general) appeals to a global audience, the tests to which it is subjected are numerous and thorough. (Unlike Ogotemmeli, we now know from direct experience what the moon is made of and how large it is.) Modern creation stories can claim to be truer than traditional creation myths insofar as the information

The day will come when the mystical generation of Jesus by the Supreme Being in the womb of a virgin, will be classed with the fable of the generation of Minerva in the brain of Jupiter. • **Thomas Jefferson (1743–1826)**

they contain has been more carefully tested, and as a result they feel true to a much wider audience. The universality and openness to testing of modern scientific accounts of the past explain a final, crucial difference: their unwillingness to invoke anthropomorphic or spiritual explanations for origins. Such explanations are ruled out by modern science because they are too flexible to provide rigorous, refutable explanations, and therefore cannot be subjected to the strict rules of testing that underpin modern science.

As this discussion suggests, world history is perhaps not so different from traditional creation myths. It, too, represents an attempt to tell the story of origins. But its audience is global, and to generate the feeling of “truthfulness” that all creation myths aspire to from a worldwide audience it must try to tell its origin stories without any taint of cultural bias, and with careful testing for rigor and objectivity.

Crusades, The

The crusades were traditionally viewed as holy wars conducted from 1095 to 1291 that attempted to liberate (from Muslim control) and protect sites in the Holy Land sacred to Christendom. Soon they took on a broader mission: defending Christian order, under the sign of the cross, against unbelievers and enemies of the church. Many twenty-first-century scholars have adopted a “pluralist” view that recognizes an Age of Crusades spanning five hundred years.

The word “crusade,” derived from the Old Spanish *cruzada*, is best translated as “an undertaking marked by a cross” and most commonly means a Christian holy war. The original goal of the crusades was the liberation of Jerusalem and other sites in the Middle East sacred to Christendom, but by the early thirteenth century the crusade had evolved into an institution of the Roman Catholic Church with a more general mission: upholding and extending Christian order against all unbelievers and enemies of the church everywhere. As a result, Latin Christian Europe came into conflict not only with the Islamic world but also with the non-Christian peoples of the Baltic, the Byzantine Empire, the Rus’ (a Slavic polity centered in Kiev), and even nonconformist Christians at home, such as the Cathars of Languedoc, the so-called Albigensian heretics. Crusading also took on a missionary element, largely due to the impetus of the new mendicant orders, specifically the Franciscans and Dominicans. Consequently, crusading zeal and objectives impelled the Roman Church to send diplomats and missionaries to Mongolia and China between the mid-thirteenth and mid-fourteenth centuries and played an equally significant role in propelling

Europe’s transoceanic voyages of discovery of the fifteenth and sixteenth centuries. Likewise, Catholic Iberia’s overseas policies in the Americas, along the coastal shores of Africa, and in South and East Asia were colored by crusading values.

Historians debate the dates encompassed by the crusades and the crusaders’ theaters of operation. One school, known as the “traditionalists,” limits the crusades to the period that began with the calling of the First Crusade in 1095 and ended with the destruction of the last crusader strongholds on the mainland of Syria-Palestine in 1291. Traditionalists further limit the crusades to holy wars fought between Latin Christians and Muslims in the Middle East and North Africa during these two centuries. For the traditionalists, true crusades had Jerusalem and the rest of the Holy Land as their exclusive focal points. The other school, known as the “pluralists,” which is in current ascendancy in scholarly circles, has a broader view. Pluralists count as crusades the Spanish Reconquista, holy wars launched against pagans and other perceived enemies in the Baltic and Eastern Europe, and wars called by the papacy against heretics and political enemies in Western Europe. They also greatly expand the chronological limits of the crusades, finding proto-crusades well before 1095 and a vibrant crusading tradition well after 1291. Some take the Age of the Crusades down to as late as 1798, when Napoleon captured the island of Malta from the Order of the Hospital of Saint John, a religious order that assumed military functions in the twelfth-century crucible of the crusades. The perspective of this article is pluralist, but only goes so far as seeing the struggles between Catholic Europe and the Ottoman Empire of the sixteenth and seventeenth

Crusaders (twelfth century). The renowned fresco murals at the Chapel of the Knights Templar, Cressac, France, fill all four walls of the rectangular structure.

centuries as the last vestiges of crusading. Given this span of over five hundred years, it was only natural that crusading, as ideal and reality, was in constant flux. As an idea and an institution, the crusade took a century to develop into full theoretical and institutional form—essentially during the pontificate of Pope Innocent III (r. 1198–1216). Even after it had achieved this level of coherence, crusading continued to respond to new stimuli and challenges.

Despite such evolution, certain crusade constants were in place from the beginning and remained an integral part of crusading to the end. These were: (1) the belief that a crusade was a holy war waged on behalf of Jesus Christ and given legitimacy by the Roman papacy; (2) the certainty that one achieved a close relationship with Jesus through this act of love; (3) the belief that this was also a penitential act of self-sacrifice that earned spiritual merit, chief of which was a plenary indulgence, or full remission of the church-imposed penance due for sins; (4) the fact that its participants, women as well as men, enjoyed a special, quasi-clerical status by virtue of their crusade

vows; (5) and the obligation and right to wear a cross, thereby becoming a *crucesignatus*—one signed with a cross.

Throughout these centuries of crusading, hundreds, even thousands of crusades of every size, make-up, and objective were launched. In light of the personal nature of crusading—a penitential act of love and sacrifice—arguably every crusader was a crusade unto him- or herself. Given this reality, medieval Europeans did not assign numbers to their crusades—not even the major ones. Western historians of the nineteenth and early twentieth centuries, however, laboring under the assumption that true crusades were only those that were directed toward the liberation or defense of Jerusalem, could not resist the temptation to enumerate what they considered to be the major crusades, but even then they were not able to reach complete consensus regarding how they should number the crusades that took place after the first five, namely after 1221. Some counted seven major crusades between 1096 and 1272; others, as this article does, counted eight. Each was a large, papally blessed expedition that had as its intended mission (regardless of what diversions it might have taken) the engagement of Muslim enemies in or around the Holy Land. That noted, we can gain perspective on the inadequacy of this numbering system by first looking at a series of crusades in Iberia that are not counted among the canonical eight.

The Reconquista: Iberia's Crusades

The crusades can be said to have roots in the struggle in Iberia between Christians and Moors. In April 711 an Islamic force crossed the strait separating Africa and Spain, and by 715 most of the peninsula, except for the northwest, was in Muslim hands. Christian counterattack, however, was underway by century's end. These earliest battles were not crusades, but they were the opening rounds of the Reconquista, a series of Iberian wars between Muslims and Christians that became official crusades in the early twelfth century and lasted down to 1492. These early struggles, particularly those of the eleventh century, provided a

model for the First Crusade. In 1064 an army of Spaniards and French captured and plundered Barbastro, with the support of Pope Alexander II, who offered the soldiers a plenary indulgence for their efforts.

As Spain was the land that gave the papacy inspiration for the crusade, it was fitting that in 1118 Pope Gelasius II granted unambiguous crusader status to an expedition against Muslim Saragossa. For the almost four hundred years that followed, Christian crusaders, both Spanish and foreign, waged holy war against a variety of Islamic powers in the peninsula. In the process, crusading left a deep imprint on Iberian Christian culture. Finally, on 2 January 1492, the combined crusader forces of the Catholic monarchs, Ferdinand II of Aragon and Isabella I of Castile, captured Granada, the last Moorish stronghold on the peninsula.

One of the witnesses of the Catholic monarchs' triumphal entry into the city on 6 January was a Genoese sea captain who understood that now, with the dream of the total reconquest of Spain realized, the Catholic monarchs might fund his enterprise to reach the court of the Mongol Great Khan of Cathay by sailing west, little realizing that the Mongols had been

thrown out of China in 1368. In their ignorance, Columbus and many others believed that reestablishing direct contact with the Great Khan would be a positive step toward the recovery of Jerusalem—a natural extension of the victory at Granada.

The Jerusalem Journey: The "First Crusade"

In response to pleas for help from the Byzantine emperor, Alexius I, whose lands in Anatolia (present-day peninsular Turkey) were being lost to Seljuk Turkish advances, Pope Urban II delivered a sermon at Clermont in France on 27 November 1095 calling upon the knighthood of the West to aid the Christians of the East and also to liberate Jerusalem. Convinced that "God wills it," the pope offered everyone who made the journey to the East a full indulgence. Thus was born the First Crusade in 1096, a phenomenon that many Western contemporaries referred to as the "Jerusalem journey" and saw as a special type of penitential pilgrimage—an armed pilgrimage with military as well as spiritual objectives.

Between 1096 and 1101 three major waves of crusaders, each numbering in the tens of thousands, marched east. The first and third waves met with disaster, but the second wave, known also as the Crusade of the Great Lords, managed to capture Jerusalem on 15 July 1099.

Jerusalem and a number of other key sites captured by the second wave became the nuclei for four crusader states: the county of Edessa (1097–1150); the principality of Antioch (1098–1268); the kingdom of Jerusalem (1099–1291); and the county of Tripoli (1109–1289). Although free of control from any mother country in Europe, these four states of Outremer (the land across the sea) are often cited as examples of early European overseas colonialism. Whatever they were, the four states were Western Christian enclaves in lands where the populations were predominantly Eastern Christian and Muslim.

Some intermarriage and cultural exchange on a personal level took place, as was evident in the Franks (as all Western, or Latin, Christians were known to Easterners) who were born and raised in the crusader states. Called derisively *poulains* (young colts) by newcomers from the West, these native-born colonists were often indistinguishable in dress and manners from their non-Frankish neighbors.

Italian maritime cities, most notably Genoa, Pisa, and Venice, established huge trading emporiums in such key port cities as Acre (Palestine) and Tyre (south Lebanon), from which they transported to Europe Eastern goods in unprecedented quantity. The textiles, spices, dyes, slaves, and sugar that flowed into Europe not only enriched and made possible the growing power of these three commercial giants, they also sharpened the European taste for the goods of Asia.

One taste that knew no limits was the desire for sugar. Western colonists learned from their Muslim neighbors how to grow sugarcane on large slave plantations and how to refine it. In the late fifteenth century and following, Europeans would create sugar-producing slave plantations and mills off the west coast of Africa and in the Americas, thereby radically altering the demographic and ecological faces of these lands.

Despite *poulains*, Italian merchants, and sugar production, the crusader states were not major avenues for cultural exchanges between Western Europe and the Levant (the eastern shores of the Mediterranean). The great influx of ancient Greek and Islamic learning that entered Western Europe in the twelfth and thirteenth centuries, for example, originated in Muslim Spain and Sicily and not in the crusader East.

One of the most significant consequences of the crusader states is that all four, but especially the principality of Antioch, brought their Frankish lords into direct competition with the Byzantine Empire, whose emperor claimed lordship over lands now occupied by Westerners. In one of world history's most ironic turn of events, the crusades, which began as an effort to aid Eastern Christians, ended up dividing the Byzantine and Latin branches of Christendom.

On their way to the Holy Land, early crusaders passed through Byzantine territory, and the presence of often-disorganized crusader forces in an alien land resulted in a series of misunderstandings and conflicts, some quite bloody. The result was that by the Third Crusade (1188–1192) the emperor of Byzantium, Isaac II, entered into an apparent conspiracy with Saladin, sultan of Egypt and Syria, to harass and destroy German forces crossing Anatolia. Isaac's plan failed, and the Holy Roman Emperor, Frederick I, chose not to attack Constantinople. The imperial capital was not so fortunate a little more than a decade later. Due to unforeseen circumstances, the army and fleet of the Fourth Crusade (1202–1204) found itself attacking, capturing, and pillaging the city on 12–13 April 1204. This act, and the establishment of the Latin Empire of Constantinople, which held the city until August 1261, completed the rupture between the churches and peoples of Byzantium and the West.

One of the many significant results of the Fourth Crusade was the conquest of most of Greece and the Greek islands by Western crusader forces and the establishment of the Venetians (and later the Genoese) in the Black Sea, which became the West's point of entry into the markets of Central Asia and beyond. Portions of mainland Frankish Greece, as occupied Greece is often called, remained in Western hands

until the mid-fifteenth century, and some Greek islands were Western possessions until the end of the seventeenth century.

Meanwhile, Islam and the Christian West continued to struggle in the Holy Land and Egypt. Muslim conquest of Edessa in 1144 occasioned the Second Crusade (1147–1149), which failed to achieve any success in the East but which also became the opportunity for the crusader West to expand the scope of enemies against whom it waged holy war.

Crusades in the Baltic

Soldiers of the Second Crusade (1147–1149) fought on three fronts: Iberia, where they participated in the capture of Lisbon in 1147; the Middle East, where they failed miserably in an aborted attempt to take Damascus in 1148; and the Baltic, where Christian Europe began a series of crusades of conquest, colonization, and conversion that lasted from 1147 to 1525. During these almost four hundred years, German and Scandinavian crusaders waged war against various pagan and Christian peoples along Europe's northeastern frontier. Unlike the crusades in the Middle East, the Baltic Crusades contained an overt missionary purpose. Also, unlike the crusades in the Levant and the Reconquista, the Baltic Crusades were not fought to recover land previously held by Christians. These were wars of conquest and expansion, although they were often justified as defensive reactions to cross-border incursions. Unlike the crusader states of the Latin East, lands conquered along the Baltic were systematically settled and culturally transformed, at least to the point that their indigenous peoples were converted to Latin Christianity. First Wends (a Slavic people), Livs, Letts, and Estonians, and later Prussians and Finns, underwent conquest, dispossession, colonization, and conversion.

Not all of the Baltic Crusades ended in success. Due to intensified animosities between Rome and Constantinople, by the early thirteenth century the Roman Church considered all Christians who followed the Byzantine rite, including Russians and Ukrainians, to be schismatics who rejected the God-ordained authority of the Roman pope. Consequently,

from 1240 to 1242 Swedish, Danish, German, and Estonian crusaders participated in a series of papally authorized expeditions against the Christian Rus'. Led by Prince Alexander Nevsky of Novgorod, the Rus' threw back the invaders in 1242.

Reconquering Jerusalem

On 2 October 1187 the armies of Saladin retook Jerusalem and came close to driving the Franks totally into the sea, thereby occasioning the Third Crusade (1188–1192), the Crusade of the Kings, so-called because of the involvement of King Richard I Coeur de Lion (Lion-Hearted) of England, King Philip II of France, and Emperor Frederick I of Germany and Italy. The Third Crusade was unable to recapture Jerusalem, but it did reconquer significant portions of the Syrian-Palestinian coast, thereby giving the truncated crusader states another century of life. The capital of the kingdom of Jerusalem now shifted to the port city of Acre.

The North African Campaigns

By the end of the Third Crusade, Western strategists understood that Jerusalem could not be won without first conquering Egypt, the heart of the empire bequeathed by Saladin to his heirs. The main body of the Fourth Crusade (1202–1204) was headed for an assault on Egypt before it was diverted to Constantinople. The Fifth Crusade (1217–1221) reached Egypt, where it enjoyed early success, but then ended in disaster. The same was true of the Seventh Crusade (1248–1254), whereas the Eighth Crusade (1270–1272), the West's last major crusade before the fall of the crusader states, ended anticlimactically after the death outside Tunis of its principal leader, King Louis IX of France, the thirteenth century's most celebrated crusader, whom the Roman Catholic Church canonized as a saint in 1297.

New Types of Crusades

The only thirteenth-century crusades to the East to succeed in rewinning Jerusalem were the Sixth

Crusade (1227–1229), in which Emperor Frederick II successfully negotiated the transfer of Jerusalem into Frankish hands (1229–1239), and the so-called (and unnumbered) Barons' Crusade (1239–1241), in which crusader leaders again negotiated the return of Jerusalem, which Islamic forces had taken back in 1239. This time Christians held the city for only three years. In 1244 Muslim mercenaries out of Central Asia, the Khorezmian Turks, whom the Mongols had driven west, recaptured Jerusalem in a bloodbath, and the city remained in Muslim hands until 1917.

In the early thirteenth century the Roman papacy began to employ full-fledged crusades to fight enemies at home—heretics, such as the Cathars of southern France (the Albigensian Crusade of 1209–1229), and political enemies who threatened papal secular authority in Italy, such as Emperor Frederick II and his descendants (1240–1269). Crusades such as these continued well into early modern times, in such incarnations as the five Anti-Hussite Crusades (1420–1431) and various Holy Leagues formed by the papacy in the sixteenth century.

The Mongols

On another front, the thirteenth-century papacy sought first to launch crusades against and then to ally with a new force from the East—the Mongols, who overran large portions of Christian eastern Europe in a campaign that lasted from 1236 to 1242. Fortunately for the West, the Mongols withdrew back to the Volga in 1242. This withdrawal took place, however, only after they destroyed a combined Polish and German army and then a Hungarian army.

Tales of atrocities convinced western Europeans that the Mongols were the forces of the Antichrist as foretold in the Book of the Apocalypse. In response, Pope Gregory IX called a crusade against them in 1241, and his successor Innocent IV renewed it in 1243, but both were futile gestures. Western Europe was too engaged with internal struggles, namely papal crusades against Frederick II, to rouse itself against a foe, even a demonic foe, that had mysteriously retreated.

Fearing the Mongols would return, the pope and King Louis IX of France dispatched several missions

Anonymous. *The Fall of Tripoli to the Mamluks*. The battle occurred in April 1289; the painting dates to the late thirteenth or fourteenth century.

to them. Beginning in 1245 and lasting to 1255, the embassies were charged with discovering Mongol intentions and converting these so-called devil's horsemen to Catholic Christianity. The envoys, who were mainly Franciscan friars, encountered only Mongol indifference. To the Mongol mind, the West had only one option: submission.

Following the Mongol capture of Baghdad in 1258, these horsemen from the steppes of inner Asia drove as far west as northern Galilee (in modern Israel), where an Egyptian army defeated and turned them back at the Battle of Ayn Jalut in 1260. Given this setback, the Mongol *il-khans* (rulers subordinate to the Great Khan) of Persia were now willing to discuss an alliance with the Christian West against Islamic Egypt. Because the Mamluk sultans of Egypt were placing increasing pressure on the rapidly deteriorating crusader states, the West was willing to ally with

the Mongols against Islam, provided they converted to Christianity. With this dream in mind, King Louis IX of France set off on his ill-fated Eighth Crusade, confident that he and the emir of Tunis, who presumably would convert to Christianity, would link up with the Mongol *il-khan* of Persia, and together they would liberate Jerusalem.

In 1287 the *il-khan* of Persia dispatched an ambassador to the West to offer yet another alliance proposal. Known as Rabban (Master) Sauma, the envoy was a Turkish monk and native of northern China who belonged to the Assyrian Church of the East, an ancient branch of Christianity known incorrectly to those outside its fold as “Nestorianism.” Sauma met with the kings of France and England, as well with Pope Nicholas IV, and received warm expressions of encouragement from all three. He left Rome in April 1288 with several papal letters for the *il-khan*. Shortly thereafter, in 1289, the pope sent Friar John of Montecorvino to the *il-khan*’s court. Before anything could come of these negotiations, the *il-khan*, Arghun, died, and his successor embraced Islam in 1295. All hopes for a Mongol-Latin crusade were dashed.

Rebuffed by the Mongol *il-khanate* of Persia, Friar John set off for the court of the Mongol Great Khan in China in 1291, arriving there, by way of India, in 1294 or 1295. Too late to meet Khubilai Khan, who died in 1294, the Franciscan friar set up a mission church in the Mongol capital of Dadu, also known as Khanbalik, which was located in the heart of present-day Beijing. This mission, which later spread to southern China, enjoyed imperial protection until the Chinese evicted the Mongols in 1368. Although the succeeding Ming dynasty (1368–1644), which reasserted Chinese rule, was hostile to all foreign elements associated with the hated Mongols, this mission church probably continued to exist until the late fourteenth or early fifteenth century. In its more than a century of existence, the mission attracted only a few Chinese converts, but it served resident merchants from the West—largely Italians—and it also succeeded in convincing a number of “Nestorian” Turks to accept the authority and rites of the Roman Church.

After 1294–1295 the Mongol Empire underwent substantial changes for the worse, and before the

fourteenth century ended, the empire was dead. Christian Europe, however, was unaware of the Mongol Empire’s fate and never forgot the dream of linking up with the Great Khan. Many motives drove Columbus to sail west toward the Indies, but certainly one of them was the dream of a crusade alliance with the Mongols against Islam.

Early Modern Explorations and Colonization

Similar crusade motives helped drive Portuguese explorations along the African coast. Henry, prince of Portugal, known as the Navigator (1394–1460), used the resources of the Order of Christ, a Portuguese crusader-military order founded in 1319, to finance the fleets that he sent out. The prince, who crusaded in North Africa in 1415, 1437, and 1458, justified this use of crusade-dedicated resources because, as his contemporary biographer, Gomes Eannes de Azurara, noted, he wanted to know the extent of the lands held by the Muslims, and he sought yet-unknown Christian princes who would ally with Portugal in the struggle against Islam.

In like manner, although the Spanish conquistadors who conquered major portions of the Americas and the Portuguese adventurers who sailed though the Indian Ocean were driven by many motives, not least of which was a desire for gold and glory, it is not difficult to find in their accounts crusading themes and sentiments that were already more than four hundred years old.

Afonso Albuquerque, Portuguese viceroy of India, a *commendador* of the Order of Santiago, an Iberian crusader-military order that had been founded in León in 1170, and who had fought Muslims in Morocco, the Atlantic, and Italy prior to going to the Indian Ocean, won a singular victory over an Arab fleet off of Hormuz in 1507. According to a posthumous compilation of his papers, when Albuquerque’s sailors fished the bodies of Muslim sailors from the waters, they found about eighty who had been killed by arrows, although no one in the Portuguese fleet had possessed a bow or knew how to use one. The source then notes: “It seems that Our Lord desired

on that day to perform this miracle so that He might show the captains, who shrank from engaging in this business, how certain of victory over their enemies are they who fight with true faith against infidels.” That putative miracle and sentiment could just as easily have been recorded and expressed by any chronicler of the First Crusade. But a sixteenth-century poet, Luís Vaz de Camões, who had lost an eye fighting Moors in North Africa, was as impressed by this reported incident as any twelfth-century crusade historian would have been. He noted in his great national epic, the *Lusiads*, which placed the exploits of Portuguese mariners in the Indian Ocean into the context of the crusades, that this miracle showed “How God will fight for them who fight for Him.”

Cultural Areas

Social units with similar features—such as language, religion, kinship, or subsistence practices—are often associated with particular geographic regions. These cultural areas can vary greatly in size, and often the affinities that bind a cultural group transform over time due to migration, diffusion of ideas and practices, and intermarriage. Despite these difficulties, the concept of a cultural area can be useful in describing certain historic groups.

Human cultural groups, however defined, can always be historically traced to particular places and generally remain associated with specific geographical areas. Such *cultural areas* can be defined at a broad range of spatial scales. In tribal social formations, a distinctive cultural group might encompass no more than a single village, whereas in complex societies an identifiable cultural group can extend across millions of square miles. Far-reaching cultural areas, however, can always be divided into smaller (sub)cultural regions. By the same token, small cultural groups can usually be agglomerated to yield larger, if less coherent, cultural areas. As a result, no unambiguous criteria for fixing the scale of cultural and geographical areas have ever been established. How such areas are defined and bounded depends on the context.

Historically, the most important criteria for differentiating cultural areas have been affinities deriving from language, religion, kinship, and subsistence practices. Often, these different attributes of social life reinforce each other, giving rise to more or less holistic cultural assemblages. In other circumstances, however, they may run counter to each other.

A linguistic community, for example, may be split by differences of faith, whereas a region united by religion may be divided by language. The multifaceted nature of human culture thus confounds the delineation of discrete cultural and geographic areas.

Even relatively nonambiguous cultural groups may be difficult to geographically bound. Cultural patterns usually morph gradually over distance, and even if the change is abrupt, border zones typically have their own personalities. Both the constitution and the distribution of cultural groups, moreover, transform over time, owing to such processes as migration, diffusion of ideas and practices, and intermarriage. Disjunct cultural assemblages, in which a single group occupies a number of separate territories, may result. Conversely, in cosmopolitan environments, a single city may contain a welter of distinctive cultural communities, which may or may not occupy identifiable neighborhoods.

As a result of such complexities, the delineation of geographically bounded cultural areas is always a matter of approximation. Different authors can construct divergent but equally valid regionalization schemes, and even a given author might map dissimilar cultural areas in the same place depending on the issues being considered. Further complications result from the fact that the peoples under investigation may employ their own systems of cultural classification and geographical division.

Cultural and Natural Regions

In earlier decades, scholars often linked cultural groups tightly to their physical environments, delineating distinctive regions that were purportedly

The U.S. anthropologist Clark Wissler (1870–1947) designated the Plains cultural area of indigenous North America, grouping tribes that shared distinctive traits.

definable by both human and natural criteria. The underlying postulate was that different climates demanded different ways of life, giving rise to distinctive cultural assemblages. This form of analysis was carried out most fully in regard to pre-Columbian North America, where ethnographers mapped a series of extensive, environmentally determined cultural regions. The mild, humid area extending from

northwestern California to southeastern Alaska, for example, was identified as the province of the Northwest Coastal Indians. Here, an abundance of wood and salmon, coupled with a paucity of most other resources, led to a distinctive maritime way of life. The constituent tribes of this region spoke languages belonging to a number of unrelated families, indicating origins in distant places. Coming together in this

particular environment, where they faced the same challenges, they were thought to have necessarily developed a common cultural system, albeit one marked by localized particularities. Similar arguments were made about the culturally similar inhabitants of the other natural regions of North America.

One key question remained open: were the cultural similarities that characterized such areas the result of adaptation to particular natural environments, or had they arisen less systematically from proximity and exchange? In some parts of pre-Columbian North America, groups belonging to distinct cultural traditions inhabited the same places, casting doubt on the environmental determinism implicit in the “cultural and natural areas” model. In the Southwest, for example, the agricultural “Pueblo” Indians belonged to one cultural complex while the hunting and gathering Apaches, who were more recent immigrants, belonged to another. Later scholarship, moreover, tended to question whether the cultural unity of these naturally defined areas extended much beyond narrow issues of subsistence.

Cultural and Linguistic Areas

In certain circumstances, the spread of a single population over a large territory can give rise to a relatively coherent cultural area. Since the expanding population carries its language with it, cultural areas of this type are linguistically marked. A notable example is Polynesia, which covers a vast expanse of the Pacific, from New Zealand in the southwest to Hawaii in the north to Easter Island in the southeast. All Polynesians are descended from a single ancestral population, all have similar (although not identical) cultural patterns, and all speak closely related languages. But while Polynesia is one of the world’s clearest examples of a cultural region, even it has some fuzzy boundaries. Polynesian “outliers,” for example, are encountered on a few small islands that lie within the bounds of the so-called Melanesian cultural realm, whereas in the case of Polynesian Tonga and neighboring Melanesian Fiji, cultural interchange has resulted in striking hybridity.

Large cultural groups established by descent from a common ancestral population tend to fade over time in the absence of unifying institutions or political systems. Social intercourse with neighboring peoples along the frontiers, the drift of cultural evolution, and the challenges of living in different natural environments result in gradual divergence. Linguistic families, which by definition derive from single ancestral groups, therefore seldom form coherent cultural areas. While one can, for example, map a family of Turkic languages over vast expanses of Eurasia, it is difficult to correlate this with any sort of distinctive cultural patterns—although politically motivated attempts to do so, under the guise of pan-Turkism, have been made. One group of Turks, the Sakha (or Yakuts), for example, left their pastoral Central Asian homeland long ago for the forests of central Siberia, where they came into contact with the Evenki and other taiga dwellers. Although aspects of a proto-Turkic culture are found among the Sakha, their cultural attributes in general are quite distinctive from those of other members of their linguistic family. The Sakha are further differentiated from most other Turkic peoples by the fact that they did not adopt Islam and were never influenced by the cultural norms of Persian civilization. Among most Central Asian Turks, on the other hand, Persian and Islamic influences were strong enough to generate, according to the sociocultural anthropologist Robert L. Canfield (1991), a distinctive Turko-Persian cultural sphere.

As the “Turko-Persian” example shows, among state-level societies common political or religious institutions can cement together previously distinct peoples, spanning linguistic and environmental divides to generate novel agglomerations. Due to the presence of such integrating mechanisms, complex societies often span larger cultural areas, and more stable ones, than small-scale social orders. Yet even in the case of well-integrated, complex societies, cultural areas change their contours and structures over time. The historical geography of human civilization reveals a continual melding and reconfiguring of cultural assemblages over space.

Cultural Areas in the Ancient World

Lower Mesopotamia, the world's first locus of urbanism, provides a good example. In this well-demarcated area, independent Sumerian-speaking city-states initially formed a coherent cultural sphere. Over time, however, aspects of Sumerian civilization (including urbanism, literacy, and religious ideas) spread to neighboring peoples, such as the Elamites and the Akkadians, who spoke non-Sumerian languages. Eventually, Sumerian itself disappeared, but many elements originally associated with Sumerian culture, such as cuneiform writing, had diffused over a broad zone, extending from the eastern Mediterranean to the Iranian Plateau. As a result, the Bronze Age Near East can either be depicted as encompassing a single cultural area or as being divided into numerous smaller regions. Ancient Egypt, on the other hand, partially isolated by intervening deserts and usually unified politically, formed a more stable cultural zone. But even in this case, not all cultural boundaries were clearly marked. Nubia, for example, situated up the Nile River beyond several imposing cataracts, shared many aspects of Egyptian culture while developing along its own political lines.

As the ancient Greeks borrowed extensively from both the Egyptians and the Phoenicians, one can place the classical Greek world within the ambit of an "Eastern Mediterranean" cultural sphere. At a finer scale of analysis, however, the Greeks occupied their own cultural area. They were unified by a common language and literature, by common religious ideas and cultic practices, and by common institutions, such as the Olympic games. Although they often stressed their own division into dialect-based subcultures (Ionians, Dorians, Aeolians, and so on), supposedly descended from separate ancestral groups, the Greeks also emphasized their cultural unity. The cultural area associated with Greek civilization was, from a land-based perspective, geographically discontinuous, spread over much of the northern and part of the southern Mediterranean littoral, as well as the Black Sea. The territorial boundaries of the Greek world were never without controversy. Debates raged,

and still occasionally flare, over whether nonurban peoples speaking Greek dialects, such as the Macedonians, should really be considered Greek. The position of non-Greek but extensively Hellenized areas, such as Caria in Asia Minor, also remained ambiguous.

The Greek world, for all of its cultural bonds, was never politically united. Virtually all of it, however, would later be subsumed within the Roman Empire. The Roman Empire in its heyday lacked the linguistic, cultic, and quotidian features that unified the Greek sphere. But common political institutions, culminating with the granting of Roman citizenship to all free males across the empire in 212 CE, did forge a kind of unity, and it would do injustice to the empire to deny it status as a cultural area. Cultural union deepened with the spread of Christianity even as political cohesion faltered in the fourth and fifth centuries. At the same time, the diffusion of Christianity outside of the empire, and its subsequent adoption as the religion of state in Nubia, Ethiopia, Armenia, and Georgia, enlarged while simultaneously diluting this cultural domain. The division of the empire into Eastern and Western segments in the fourth century, followed by the divergent political and religious trajectories of Rome and Byzantium, gradually reconfigured the cultural geography of the entire area. Some scholars argue that the main cultural divide in Europe today is that separating the West of Catholic and Protestant Christian heritage from the East of Orthodox background—a division that is sometimes dated to the fourth-century partition of the Roman Empire.

Asian Cultural Areas

In east Asia, an extensive cultural area emerged through a combination of political might and the diffusion of literacy and ideology. Confucianism, Mahayana Buddhism, and a belief in the preeminence of the Chinese imperial system were key features of this emergent sphere. As the Chinese state expanded south of the Yangzi (Chang) Valley during the Han dynasty (206 BCE–220 CE), these cultural patterns

spread with it, as far south as northern Vietnam. Although Vietnam was to reclaim its independence in the tenth century CE, it remained within the orbit of “Confucian Civilization,” continuing, for example, to employ the Chinese ideographic writing system until colonized by France. To the east, Korea came under the influence, both political and cultural, of China, especially during the Tang dynasty (618–907 CE). Although Japan never succumbed to Chinese rule, it too adopted many aspects of Confucianism, the Chinese writing system, and a host of other ideas and practices of Chinese provenance. The cultural commonalities so generated have proved long lasting. Today, many scholars depict an East Asian cultural area composed of China (excluding Tibet and Xinjiang), Korea, Japan, and—in some versions—Vietnam.

In South Asia, by contrast, an extensive cultural area emerged in the absence of political unification. During the first millennium BCE, the complex of religious ideas and practices now known as Hinduism began to coalesce in the Ganges Valley and then spread across the rest of the Indian subcontinent. By the early centuries of the common era, South Asian forms of high culture had diffused through much of Southeast Asia as well. This evolving cultural region was fused together by common spiritual ideas (such as the transmigration of souls), caste ideology and practices, and the use of Sanskrit as a sacred language of the elite. Many of its key features were to be challenged internally by Buddhism and externally by Islam, resulting in additional rounds of cultural transformation and geographical reconfiguration. Eventually, Southeast Asia was to be largely detached from the field of South Asian cultural influence. Some scholars would argue the same for present-day Pakistan, emphasizing the distinctiveness of its overwhelming Muslim population. Those who regard Pakistan as remaining within a culturally defined South Asian region, on the other hand, point to the fact that many aspects of everyday culture—such as diet, music, and language—continue to tie together the

peoples living on either side of the India–Pakistan border.

The Historical Emergence of New Cultural Areas

The spread of Islam during and after the seventh century demonstrates how new cultural areas can emerge explosively, linking together formerly separate regions through both cultural synthesis and the spread of novel ideas. As Islam fused both a legal code and a set of political ideals with religious beliefs and practices, it proved particularly potent for generating a new, dynamic culture area. In the process, the previously distinct Persian zone was substantially merged with that of the Arabic-speaking world, although in many respects Iran retained its cultural distinctions. As Islam expanded, it came into contact with many different cultural traditions, resulting in the development of numerous hybrid forms. Debates are therefore conducted over whether an “Islamic cultural area” should be limited to the historical core of the Middle East and North Africa or whether it should cover the entire Muslim world. Such disputes are made more complex by the contemporary spread of more orthodox forms of Islam into peripheral areas, such as Java, that were formerly marked by profound syncretism.

European imperialism also created in a relatively brief span a number of distinctive cultural areas. Today, for example, Africa is often divided into Francophone, Anglophone, and Lusophone (i.e., Portuguese-speaking) zones, based on the languages of elite and official communication. Similarly, Latin America is usually mapped as its own cultural area. But, as in the case of other culturally defined regions, “Latin America” is not without controversy. Argentines, for example, have often wanted to emphasize their European roots at the expense of a pan–Latin American identity, whereas many scholars now argue that in large portions of South and Central America, the indigenous cultural imprint remains more substantial than the “Latin” one.

Areas or Networks? New Geographical Approaches

As the example of Latin America shows, the mapping of cultural areas is always ideologically fraught and intellectually challenging. As a result, many scholars now prefer to avoid positing discrete cultural areas of any sort, preferring to emphasize cross-cultural networks and patterns of globalization. This is especially true in regard to the contemporary world, supposedly characterized by a postmodern condition of constant flux and the continual transgression of all purported boundaries. Yet even in ancient times, similar processes operated, leaving all cultural areas unstable in content and uncertain in extent. Cultural areas are thus perhaps best thought of as geographic constructions rather than as preexisting entities that can be discovered through empirical analysis.

Culture

The term *culture* has been broadly used to denote the identity-shaping beliefs, activities, institutions, and artifacts resulting from human interaction. Cultures are subject to constant change over time from environmental forces, political struggles, and social inequalities. Although human populations may bond through shared cultural features, cultures themselves can resist easy categorization when they exhibit human actions that are contradictory, ambiguous, and disorderly.

The concept of culture occupies an important place both in academia and everyday usage. Since culture means so many things at once, it is hard to define in simple terms. In fact, one 1960s text noted that there were at least 150 definitions of the term in use. The term has for long been used in a variety of contexts to describe the activities, beliefs, institutions, and artifacts produced out of the interactions among human beings. Culture understood in terms of meaningful actions can be located among both human and nonhuman species. Among humans, culture can be located at many levels of human interaction, from the smallest of human groups (such as a nuclear family) to successively larger units of human organization (communities, tribes, ethnicities, societies, nations, and civilizations). It is culture that imparts a sense of identity to human beings.

Perhaps it is the discipline of modern anthropology that has been expressly concerned with defining the term. Over the past hundred years or so anthropologists have debated the relevance of this term and generated a variety of definitions on both sides of the Atlantic. Some, like David Schneider, Claude Lévi-

Strauss, and A. R. Radcliffe-Brown, despite differences, tended to view culture in terms of underlying structures whose order could be uncovered. Others like Ruth Benedict and Margaret Mead associated culture with personality types. After World War II, greater attention began to be focused on the changing and disorderly aspects of culture that had for long been ignored by most anthropologists. Scholars like Clifford Geertz and the Comaroffs (John and Jean) began to study culture in terms of the meanings and symbolic actions of human beings over time.

Today, there is a general consensus that cultures are profoundly shaped by history, that is, they are subject to constant change over time. Cultures are shaped by environmental forces, political struggles, and social inequalities. Cultural features might be widely shared among human populations. At the same time, they may also exhibit human meanings and actions that are contradictory, ambiguous, and disorderly, and which resist easy categorization.

Culture and the Study of World History

The concept of culture occupies a prominent place in the writings of world historians. So pervasive is the presence of this concept in the study of world history that even if not explicitly used or defined, it usually forms the basis for the understanding of many associated concepts such as society, nation, civilization, regime, and world system. World historians frequently use *culture* to highlight the unique features, achievements, and activities that characterize these human groups. The term has also been extended to distinguish broad patterns of sustained interactions between societies. Obviously, much depends on the

A church in Port Moresby, Papua New Guinea, features traditional cult-house designs.

particular focus, method, objectives, and audiences of the writers in question. Despite the widespread use of the term, however, world historians have yet to subject it to sustained theoretical reflection. In general, depictions of culture in world history tend to take shape within three broad types of writings, namely, universal histories, themed world histories, and microlevel world histories.

Universal Histories

Universal histories have found expression in a number of works since the nineteenth century. Such works have typically been interested in developing grand-scale interpretations about the rise and fall of

civilizations in human history. Borrowing extensively from such fields as archaeology, cosmology, economics, geology, politics, and sociology, writers such as Oswald Spengler (1880–1936) and Arnold Toynbee (1889–1975) produced synoptic histories of the world that transcended national histories. These writers were primarily concerned with uncovering laws that governed the rise and fall of civilizations. Their accounts of the history of the world became the study of birth and demise of organic and bounded units called civilizations.

In these universal histories, culture often became equated with the political, intellectual, and artistic achievements that defined civilizations. Oswald Spengler made distinctions between civilization and culture, indicating that the former represented the latter in its last stages prior to its plunging into decline. For others, the role of culture was subordinated to the influence of the economy and class struggle (in the case of Karl Marx and Friedrich Engels) or to abstract notions of a progressively advancing universal human spirit (in the case of G. W. F. Hegel). Given the scale of interpretation and the sweeping generalizations being made, it is hardly surprising that there was little explicit theorization of culture. The minute details of cultural production and transformation were invariably ignored in favor of making broad statements about the characteristic features of civilizations. Europe and the elite classes received a greater share of attention than did other parts of the world or more oppressed populations. Although treatments of culture remain to be fully developed in such accounts, ambitious world histories of this genre continue to be written, and with impressive (though sometimes controversial) results. Notable instances of such work can be found in Max Weber's work on the connections between the Protestant ethic and the rise of a capitalist ethic in western Europe. More recently the works of David Landes and Samuel Huntington continue in this idealist vein with "culture" driving economic development and political conflict on a world historical scale.

Japanese print, mid-1800s. Cultures collide as an Englishman dances to *shamisen* music.

Themed Histories

Following World War II world historians began increasingly to concentrate on specific themes of world historical significance. They examined specific human activities and patterns of interactions (political conquests, long-distance trading, nomadic migrations, the spread of religions) that could be discerned over long periods of time and vast regions of the earth. The focus was on themes of global significance rather than on constructing grand accounts of the world that tried to explain the whole of human history within a single intellectual framework.

One set of writings tried to gauge the production, transmission, and experiences of social and economic

inequality between nations. In the 1960s and early 1970s, a number of scholars took up projects that tried to explain the rise of the West and the continued modernization (or lack thereof) of the world's nations through economic development. The treatment of culture in such accounts was uneven. In some writings culture became a residual category, where activities pertaining to the arts, literature, and the intellect, were deposited. In others, the role of culture was subordinated to the study of political and economic forces. Once again, there was an excessive focus on Europe.

Over the past decade or so the terms of this debate have changed considerably as scholars began to write more sophisticated and non-Eurocentric studies examining why Europe's history diverged so drastically from that of the rest of the world. Greater economic agency and centrality have been given to other parts of the world, especially Asia. These historians have usually given primacy to political and economic factors when explaining the great divergence in the development of European and non-European societies since the eighteenth century. Few writers give preeminence to culture as an important determinant of the great divergence between Europe and the rest of the world (but see David Landes's 1998 *The Wealth and Poverty of Nations*). In this genre of writings culture has come to stand for attitudes, ideologies, and values that distinguish one society from another.

In the 1970s another genre of world-historical writings began to emerge that focused on world-systems analysis. Operating on many levels and over many time periods, these scholars tried to map the economic connections that linked vast regions of the globe. The emphasis once again was on the role of political, social, and economic factors in the formation of global patterns of economic exchange. In Wallersteinian world-system studies, it is the nature of the world system that shapes culture, which usually leaves culture as the ideological by-product of capitalism (see Immanuel Wallerstein's 1991 *Geopolitics and Geoculture: Essays on the Changing World System*).

Another focus of world-history studies has been cross-cultural encounters. These writings examine processes that transcend geographical and political

boundaries to connect societies or cultures spread over vast distances and times. Some of the most interesting writing on culture in contemporary world history has its roots in this influential body of work. These writers convincingly argue that cross-cultural connections have been one of the principal agents of change, with far-reaching consequences for our planet's history. Over millennia, such cross-cultural flows have resulted in the movement of peoples, ideas, objects, and even microbes over vast regions of the planet, connecting and transforming diverse societies. Studies have examined ecological exchanges, technology transfer, trade networks, migrations, religious conversions, circuits of pilgrimage, processes of imperialism and globalization, and frontiers as zones of exchange. The works have moved from simple explanations of one-sided diffusion to two-way processes of mutual exchange and transformation. Yet while the phrase *cross-cultural interactions* finds frequent expression in world historical writings, there is little discussion about what is cultural about these interactions. In many writings *culture* becomes a synonym for *society*. In others, the term *culture* may be used to refer to human activities, such as migration and conquest, through which ideas, objects, and peoples are exchanged. But while the interactions between cultures are mapped in detail, most world historians have hesitated to provide conceptual clarifications for the term *culture* that take into account wider debates in other fields (though there are exceptions).

This is not to say that engagements between disciplines such as history and anthropology have yet to take place. After the 1970s, the traditional boundaries between anthropology and history began to dissolve as scholars realized that culture and history could not be separated. Historians began to read the works of cultural anthropologists, works in which culture was seen in terms of the meanings embedded in human interactions. In the decades that followed there was considerable debate about the politics of ethnographic writing, and even about the salience of the term *culture*. This brought the concept of culture to the center of academic debate and writing. These developments, along with borrowings from poststructuralist and

postcolonial writings in the 1980s and 1990s, served to bring about a democratization of history and anthropology that resulted in the inclusion of the voices of women, minorities, and oppressed peoples. Sensitive accounts of the dynamics of culture, power, history, and resistance followed. The combined result of this intellectual ferment was the emergence of a new genre of sophisticated writings that is sometimes called the “new cultural history.” Culture was no longer seen as static and organic but as highly factor-centered, ordered, even intuitive, and yet prone to moments of disorder and flux. In these new writings there is increased emphasis on microlevel studies of the creation, transmission, and experience of culture within specific historical contexts.

Microlevel Histories

The rise of the new cultural history has allowed the emergence of a third genre of culturally oriented scholarship in world history, one that explores world-historical themes through microlevel analyses that show the interpenetration of global and local forces. Unlike in past scholarship, global forces are not seen as occupying some higher level of existence that is separate from local forces. The new approach proposes that global forces manifest themselves in local situations in the everyday lives of people within specific historical contexts; the study of culture becomes the study of the interpenetration of the global and the local. Writings of this genre have focused on themes such as conversion, colonialism, globalization, and capitalism. They provide sophisticated treatments of culture—now viewed as a shifting arena of meanings and actions shaped in a variety of historical contexts. The emphasis is on revealing the complex ways in which human beings come to terms with the conditions of existence that shape their lives.

Culture and Other World Historical Traditions

The study of culture in world history will undoubtedly gradually extend to societies outside Europe that

have developed their own rich understandings of the human condition. Orally and textually preserved worldviews from non-Western societies around the world have focused on such subjects as civilizations, jurisprudence, trade, science, philosophy, politics, theology, literature, and geography. Hindu and Buddhist cosmographies, for example, constructed their own world systems based on multiple realms of heavens, hells, and various kinds of beings that interacted with human beings. Royal historians, travelers, intellectuals, and common folk from around the world have spoken and written on topics that reflected their own understandings of culture, power, and history. For instance, the fourteenth-century Islamic scholar Ibn Khaldun (1332–1406) observed in his universal history, the *Muqaddimah*, that the study of human social organization formed an essential part of the scientific study of civilization. While such works might be termed “ahistorical” by the standards of modern historical scholarship, there is an increasing awareness that such accounts need to be explained on their own terms, separate from Western traditions of historical analysis.

The Future of Culture in World History

Culture has been variously defined in relation to communities, societies, states, nations, empires, and civilizations and world systems. The descriptions of culture have ranged from the simple to the complex. While it is generally recognized that culture finds its best expression in detailed local and regional histories, there has been little discussion about the use of the term at the level of global or planetary studies. Even today, many world histories treat culture as a residual field of human activities and artifacts that cannot be labeled political, social, or economic. On other occasions it has signified the presence of broad patterns of interactions between human collectives, with little clarification on what was “cultural” about these interactions. For these reasons, a number of questions remain for world historians. Is the concept

of culture even appropriate for universal histories, with their broad sweep and general focus? Do world historians need to develop another term? What distinguishes the concept of culture from, for example, the concept of society?

Questionable too is the continued anchoring of culture to continental and area-studies schemes of world geography. More recently there have been attempts to revise these metageographical schemes and construct regions that are more representative of the cultures they claim to represent. Ultimately, the question of culture will depend on where one wants to locate the world in world history—at the level of the global, in the manifestation of broad interactions and processes, or at the level of the local. Either way, world historians writing in the twenty-first century will increasingly strive to deploy a concept of culture (or its associated terms) that attempts to represent both the particular and the general as they write about the connections that have bound human beings to one another and to their environments for millennia across this diverse planet. Culture continues to be relevant to world history, and world historians are beginning to engage the term with increasing rigor.

Currency

The use of currency aids in the exchange of goods and services by distinguishing the transactions of buying and selling from barter, setting a standard of value, and allowing the accumulation of wealth. But before an object may be used as money—whether it is a coin, bank note, shell, grain, or (in modern systems) an electronic transfer—the community must accept it as such.

Money may be defined as a set of objects whose prime use is to facilitate economic exchange. The identity of these objects and the range of functions they may perform are determined by the community in which the exchanges occur. In modern Western capitalist societies, coins and banknotes serve as money; they are issued under the authority of governments and accepted for commercial transactions by the population. Prior to modern times, traditional societies in Africa, Asia, and the Pacific and Indian oceans employed various and differing money forms; the most famous were cowry shells, whose scientific name (*cuprea moneta*) stems from the popularity of their use as money. We usually refer to earlier money forms that are not coins or banknotes as “primitive money.”

China’s monetary system employed metal objects as well as animals, produce, and shells from the twelfth century BCE, but disc-shaped coins did not appear until the third century BCE.

The anthropologist Karl Polanyi argued that money is “a system of symbols, similar to language, writing or weights and measures” (1968, 175). The members of a community, as buyers and sellers, must give the role of money to particular objects (and continue to accept them as money). But there are no objects that are of themselves “money.” A disc of metal or a piece of paper becomes money because a community accepts its value as money. This is easy to see in a modern currency system—in which coins and pieces of paper only represent the sums of money they are worth (and are termed fiduciary, or relying on trust). In the nineteenth century and earlier, coins were issued in gold and silver, and the metal was worth only a little less than the face value of the coin. But the use of gold and silver as money ultimately depends on the agreement that these metals have a value.

The Uses of Money

It is possible to recognize four main uses for money. First, and perhaps most important, money acts as a medium of exchange. It is possible to exchange (sell) an object for an agreed value in money (such as a weight in silver or a number of silver coins) and then to exchange (buy)

Wealth is often defined as a large amount of money, since it is with money that the gaining of wealth, and trade, are concerned. But at other times money seems to be nonsense and a mere convention with no real existence in nature . . . • Aristotle (384–322 BCE)

An illustration of an intricately designed copper plate of the Tsimshian Native American peoples of the northwest coast. Copper plates were traded for blankets, skins, and oil.

in a different place and at a different time very different objects or services with that money. Money thus separates the transactions of buying and selling (which are combined in exchange by barter).

Second, money acts as a standard of value. It enables the value of different objects and services to be expressed according to a set scale or measure. The value of a cow or the services of a cobbler, for example, can be compared according to their value expressed in money (such as dollars and cents). The existence of money then allows value to be expressed

in terms of a unit of account. Linked to this is the third use: money can facilitate the storage of wealth. Wealth can be stored in banks, for example, through the deposit of a quantifiable number of money objects, such as coins. Finally, money provides a means of payment. It allows precise amounts to be paid to a wide range of people for a wide range of goods and services.

Money and Coinage

The European tradition of money is firmly tied to the history of coinage. The English word *money* is ultimately derived from the Latin *moneta*, which could mean coinage as well as the mint in which coins were produced. But money does not equal coinage. While the main functions of money have remained the same, the forms of money and their roles have evolved and changed. We should resist the assumption that money has always been understood and used as we understand and use it today. The use of precious metals, as well as the use of animals and produce, as money can be traced back to the third millennium BCE. Hoards of pieces of silver, some in earthenware vessels, have been found in Sumerian and Akkadian settlements from Mesopotamia. Cuneiform writing on clay tablets from Nippur in Sumer at this time provide the earliest known records of transactions using weighed silver. Other tablets from Nippur record loans and payments valued in terms of grain or cattle. In the second millennium BCE, the Mycenaean Greeks employed cattle as a form of money; in Homer's poem *The Iliad* we find armor, for example, and even skilled craftsmen captured in war, valued in terms of oxen.

The creation of coinage was an important step in the development of money. Coins may be defined as pieces of metal that are marked with a design to show the authority under which they were issued, and which indicate that they have legal force as money. They typically conform to standards of weight and fineness, but the key aspect is that they be marked out by the issuer (who is very often the government), as money whose value is guaranteed. The kings of Lydia in Anatolia (modern-day peninsular Turkey) were the

Currency used by the Allies during World War II.

first to create such coins, probably at the end of the seventh century BCE. These issues were of electrum, a naturally occurring alloy of gold and silver, which the Lydians cast into discs and impressed with stamps on both sides. In around 550 BCE, the Lydians under King Croesus were also responsible for creating the first gold and silver coinages.

In China, a monetary system employing metals, animals, produce, and shells had been in use from the twelfth century BCE. In the late sixth century BCE the Zhou emperors began placing their names on small-scale cast-bronze farming hoes that were to serve as money. The use of disc-shaped coins did not commence till the third century BCE. The use of paper currency, however, began in China during the twelfth century BCE, but was not adopted in the West till the seventeenth century, where it arose as a solution to the shortage of coinage.

The introduction of bronze coinage in Greece at the very end of the fifth century BCE also marked an important development in the Western world. This enabled coins to be used for everyday transactions of a much lower value than silver or gold permitted. Under the Romans huge issues of small bronze coins enabled the economy of many cities and regions to be extensively monetized for the first time in world

Money can be more of a barrier between people than language or race or religion. • Vera Caspary (1899–1987)

history. The invention of coinage was not lost with the fall of the Roman Empire.

Modern Money

Today electronic banking is a key feature of money use. Credit cards are as familiar as coins and banknotes. The study of money in the modern world is primarily focused on the nature and operation of monetary systems and the factors which govern the buying power of money. Monetary systems include the public holdings of money (by individuals and businesses), commercial banks, and central banks operated by governments to facilitate official transactions and economic policy. Modern monetary theories seeking to explain changes in the value of money have been dominated by the quantity theory of money, which posits that there is a firm link between the level of prices and the quantity of money in circulation. Although ancient and medieval societies paid little attention to the nature and role of money, today it has become a consuming passion.

Cyrus the Great

(c. 550–530 BCE)

KING OF PERSIA

In the sixth century, the Persian king Cyrus founded the Achaemenid Persian Empire by conquering the Medes, Lydians, and Babylonians. He earned loyalty and respect by allowing conquered peoples to retain their religions and traditions, and he freed the Hebrews who had been held captive in Babylon.

Cyrus the Great belonged to the Pasargadae tribe who immigrated to the Iranian Plateau during the first millennium BCE and settled in the area known as “Persis” or Persia, which is the southwestern portion of the Iranian Plateau along the Persian Gulf. During the sixth century BCE the Persians took control of the areas of Anshan and Susa (in modern Iran) and installed Persians as local rulers. Cyrus himself claimed that he was king of Anshan (he became king in 559–558 BCE) and that his forefathers were kings of the same area that is now identified with Marv Dasht. Three legends are attached to Cyrus and his upbringing. The first states (from the ancient Greek historian Herodotus) that he was the son of Cambyses, son of Cyrus I. His mother was Princess Mandane, who was the daughter of Astyages, the last king of the Medes, an Iranian people. Because Astyages had been warned by omens that the boy would take his throne some day, he decided to have the boy killed. Cyrus had been given to Harpagus, a Mede, to kill, but Harpagus was not able and gave Cyrus to a shepherd, who raised Cyrus as his own son. According to Herodotus, Cyrus displayed the genius of leadership in his youth that is ultimately derived from native Persian legends. Finally Cyrus’s true identity was discovered, and he was sent to Persia, where he was able to unify the Persian tribes and create a kingdom for himself.

The second legend states that Cyrus was left in the forest and that a female dog suckled him and protected him from wild beasts. This legend clearly demonstrates Indo-European elements (compare the legend of Romulus and Remus, the founders of the city of Rome). The third legend (by Nicolaus of Damascus) states that Cyrus’s father was a bandit, who was given to a wealthy and noble family of the Median court to raise.

In 550 BCE Cyrus met Astyages in battle and won a major victory in which many of the Median forces defected to him. Now ruler of a confederation of

Profile of Cyrus the Great.

A young Cyrus the Great rides in a chariot.

Median-Persian forces, Cyrus set out to conquer the neighboring regions. He moved onto Anatolia (in modern Turkey) and faced the rich kingdom of Lydia with its famous King Croesus with his capital at Sardis. The oracle of Delphi had warned Croesus that if he fought Cyrus, he would destroy a great kingdom, which, in fact, would be his own. Sardis and Croesus fell into the hands of Cyrus in 547 BCE. This event was followed by the conquest of Mesopotamia with its chief city, Babylon, in 539 BCE. The Babylonian king Nabonidus was despised by the local population for neglecting the New Year festival and especially for neglecting the temple of the great Mesopotamian god Marduk. Cyrus entered the city almost unopposed and, as part of his policy of respecting local people and their religion and culture, made his way to the temple of Marduk. There he made offerings and paid homage to the great Mesopotamian god, presented himself as a servant of Marduk, and made arrangements for the

rebuilding of the temple. This tactic on the part of Cyrus would pay off in many parts of the soon-to-be Achaemenid Persian Empire (550–330 BCE). Unlike the Assyrians, who used brute force to subdue the local population, the Persians allowed local traditions to survive and the provinces to be autonomous, providing security and collecting taxes. At this time the Hebrews who had been held captive in Babylon (the period in Jewish history known as the “Babylonian Captivity”) were also freed and allowed to go back to their homeland. According to the Bible (Ezra 6:2–5), Cyrus decreed that the Temple of Jerusalem be rebuilt and that what had been taken away by Nebuchadnezzar (Chaldean king of Babylon) be brought back to Jerusalem. Hence, the Old Testament (Isaiah, Ezra) remembers Cyrus and the Persians kindly. In Isaiah 45:1–3 the respect and compact between Cyrus and Yahweh, the Jewish god, are mentioned, again suggesting the king’s religious liberality.

Cyrus the Great also left us a firsthand account of his tolerance and worldview, which is known as the “Cyrus Cylinder” in the Akkadian language (Semitic language common in Mesopotamia at the time). This account also reveals aspects of his royalty. He was presented with all the titles of the Mesopotamian kings, such as “a great king, king of kings, king of the Four Corners of the world.” He stated that the people had the freedom to practice their religion and live as they wished, which we could consider as the first human rights declaration. By the time of his death at the hands of nomadic Iranian people known as “Sakas” in 530 BCE in Central Asia, Cyrus had established an empire that spanned from the Iranian Plateau to the Mediterranean Sea. His tomb is at Pasargadae, the location where he defeated the

Median king and where Cyrus had his stronghold. The Achaemenid Persian Empire would further expand and last for two centuries.

The explorer Vasco da Gama is best known for his successful voyage around the eastern coast of Africa in the 1490s, which allowed Portugal to stake claim on the Indian Ocean and control half the spice trade from India. While da Gama's accomplishment brought wealth to his country, it also sparked the Portuguese use of African slaves on sugar plantations.

Vasco da Gama was among a handful of explorers who reshaped trade and labor among Europe, Africa, Asia, and the Americas. His three voyages between 1497 and 1524 opened an ocean route for trade between Europe and Asia; his three landings on the east coast of Africa in 1498, the first by a European, furthered the Portuguese goal of using Africans as a source of labor. His voyages led Portugal to dictate the terms of trade in the Indian Ocean and to enslave Africans for shipment to plantations first in the Mediterranean and islands off the African coast, then around the globe.

The early days of Vasco da Gama remain a mystery. He was the third son of Estevao da Gama, a nobleman from Alentejo, a town in southwestern Portugal. Some historians cite 1460 as the year of Vasco da Gama's birth, whereas others cite 1469. A third group of historians rejects both years, and controversy continues. Da Gama may have studied mathematics and navigation at Evora, Portugal, although again the matter is in doubt. What is clear is that da Gama might have remained a minor nobleman in Portugal. Instead ambition led him to seek fortune overseas. He distinguished himself in command against a French fleet in 1492, and three years later King Manuel of Portugal chose da Gama

to lead four ships to India, a Portuguese goal since the 1420s.

Economics and religion led Portugal to persist for nearly eighty years in its quest for an ocean route to India. At the western end of Europe, Portugal bristled at the price of pepper, cinnamon, nutmeg, and other spices after they had changed hands several times, with an increase in price at each exchange, along the land route west from India. Worse, many of the middlemen in these exchanges were Jews and Muslims, the enemies of Christendom whom the Portuguese and Spanish had banished from the Iberian Peninsula in 1492. God, country, and king, da Gama believed, had appointed him to circumvent by water this spice route controlled by infidels. After the Portuguese—devout Catholics—had the spice trade, they, rather than nonbelievers, would dictate the price of spices.

But the Genoese sailor Christopher Columbus complicated matters. In 1492 Spain had tried to beat Portugal to India by sending Columbus west across the Atlantic rather than east around Africa. Columbus believed he had reached India and was at sea again in 1495 when da Gama began to amass supplies for his voyage east. His compatriot Bartolomeu Dias had in 1488 rounded the southern tip of Africa, opening the way to India, but no one knew the distance between the two. Nor did anyone have an accurate map of the east coast of Africa. As had Columbus, da Gama sailed into uncharted waters upon leaving Lisbon, Portugal, on 8 July 1497. After more than 7,500 kilometers and ten months, the longest ocean voyage to that date, da Gama reached Calicut, India, on 22 May 1498. Da Gama led two more expeditions to India—one in 1502 and his final voyage in 1524. That September he reached Cochin, India, as viceroy

of India. He died on 24 December 1524, and only in 1538 was his body returned to Portugal for burial.

By then Portugal had established ports in Asia from Diu on the western tip of India to Malacca near the southern tip of Malaysia, giving the Portuguese control of the Indian Ocean. This control enabled Portugal to capture half the spice trade between Europe and Asia. Merchants who once sailed the Indian Ocean at will now had to hire Portuguese ships for

transit or pay a 6 to 10 percent duty to sail their own ships through the ocean.

The wealth from the trade that da Gama's voyages had made possible returned to Portugal both as money to establish sugar plantations in Portugal and on islands that Portugal controlled off the African coast and as slaves to work these plantations. Between 1450 and 1500 Portugal enslaved 150,000 Africans as plantation workers. By 1800 Portuguese, Dutch, and English traders shipped more than 20 million African slaves around the globe, many of them to the Americas. In the United States racism and poverty remain the consequences of slavery and the legacy of Vasco da Gama.

Dance and Military Drill

Moving and vocalizing together in time creates feelings of camaraderie and a willingness to cooperate among the participants. For this reason, community dance and music making—uniquely human activities—have been used probably since the origin of the species; shared rhythmic movements have played a part in religion, war, politics, and many other social settings.

Engaging in community dance and/or military drill by moving rhythmically together for lengthy periods of time is a very effective way of arousing shared and friendly feelings among the participants. This effect is reinforced by music and voicing, all the way from band music and choral singing to drill sergeants' shouts of "hut, hip, hip, four." Somehow moving muscles together in time, with voices backing up the rhythmic beat, makes people feel good, wipes out old grudges, and smooths over personal rivalries. Even when the immediate excitement subsides, such exercises leave a residue of fellow feeling and readiness to cooperate. This had important effects in times past and still exhibits itself in religion, war, politics, and innumerable social settings where people dance, sing, and keep together in time.

Exactly how shared feelings are aroused when we dance, sing, and march is not accurately known. Hormones and the sympathetic nervous system are surely involved; so are parts of the brain. Suffice it to say that such behavior and their results are both unique to and universal among human beings. Only humans engage in community dancing and music making, and all known human societies do both. Only a few, however, harnessed this human response to keeping together in time for military purposes, though those

that did so profited from the superior cooperation and morale of soldiers who drilled regularly for long periods of time.

Origins

When rhythmic dancing and music making first arose among humankind is unknown, but it must have been very early, perhaps before *Homo sapiens* emerged and before language developed among our ancestors to make us fully human. Whenever the habit established itself, the advantage of greater cooperation among large numbers that developed from dancing together must have been enormous, since only dancers survived. Observations of our closest animal relatives, the chimpanzees of Africa, suggests why this was so. In 1969, the band of fifteen adult males that Jane Goodall and her helpers were studying split into two rival groups, and in the next two years each of the seven seceding males was hunted down and killed by their rivals, who thus regained the whole of their original territory and the females who had seceded. Very slightly superior numbers (and perhaps stronger cohesion) among the core members of the old band thus prevailed. Obviously, if dancing together allowed our ancestors to overcome the sort of individual frictions that split that chimpanzee band apart, it is easy to imagine how larger numbers of more cooperative individuals could expand their territory against neighbors who had not yet learned to dance—thus making that form of behavior universal within a few generations.

Thereafter different human groups elaborated the possibilities of rhythmic movement in innumerable different ways. Until very recently, the principal

Dance is a cultural universal that translates well across cultures. In this photo Morris dancers perform at a community festival in a small New England town.

historical importance of dancing was to knit local communities together. Participants were well aware of its emotional effect. In the twentieth century, for example, Greek villagers told an anthropologist that they felt light, calm, and joyful when they danced; and Kalahari hunters reported to another observer that dancing made their “hearts happy.” Such feelings made conflict like that which ravaged Goodall’s chimpanzees far less likely, and allowed larger numbers of persons to live together peacefully year after year. Although important emotional cohesion and cooperation, induced by dance, may have been among our ancestors, nothing like a history of community dancing can be written. Such behavior was simply taken for granted, and before anthropologists started work about 150 years ago, evidence for dancing among hunters, pastoralists, and farmers remained exceedingly sparse.

Spiritual and Religious Importance of Dance

Records are more substantial for a more specialized, eventually professionalized, kind of dancing intended to consult and/or please powerful spirits and gods. Around such rituals, organized religions eventually emerged. Later on, in urban settings, expert exhibitions of dancing (and song) honoring a god also

became public entertainment for spectators, as surviving texts of Greek dramas attest. Simultaneously, excited, participatory dancing among believers remained a growing point for religions, as is clear from biblical references to how Saul and David danced before the Lord and founded the Hebrew kingdom, largely on the strength of enthusiastic bands of young men who danced with them, honoring Yahweh. Early Christianity also was hospitable to dancing, though the practice soon fell under suspicion when bishops and priests set out to restrain and ritualize public worship. Enthusiasts and heretics, who often (but not always) danced, continued to challenge church authorities from time to time; and in the sixteenth century, Protestants bound their congregations together by rhythmic movement while standing up and singing hymns and psalms. A long series of subsequent religious enthusiasts—Methodists, Quakers, Mormons, Shakers, Pentecostals, Russian Old Believers, and others—used similar methods to arouse cohesion and commitment among their followers. African Christians (and a variety of heretical faiths) have been particularly successful in using song and dance, borrowed directly from village customs, to consolidate their converts.

Song and dance kept other world religions in ferment in much the same fashion. Among Jews, Hasidic enthusiasts sang and danced, attracting a large

following in Poland and nearby lands, beginning in the eighteenth century.

Among Muslims, dervish associations of restless young men proliferated widely beginning about 1000 CE, chanting, dancing, and sometimes achieving ecstasy. Across the centuries, many Buddhist sects also engaged in rhythmic exercises, which appealed usually to poor and discontented groups.

Recent examples include the so-called Boxer rebels in China (1900–1901) and a similar Buddhist sect of dancers who began to attract official persecution in the 1990s. In Japan, the Soka Gakkai, founded in 1930, was persecuted by the imperial government until 1945,

but burgeoned after that date through daily rhythmic exercises conducted outdoors in urban settings to become a significant factor in national politics.

Tension between enthusiasm generated by dance and song and the authority of established priesthoods and legally defined systems of belief was persistent throughout religious history. Whenever social strains were acute, enthusiastic sects arose to express and relieve popular discontents, and they nearly always relied on dance and song to keep their followers together. The process continues worldwide today, with diverse, sometimes angry, so-called fundamentalist movements vigorously challenging conservative

This eighteenth-century Japanese woodblock print shows five women dancing at the annual rice planting ritual held at the Sumiyoshi shrine. Library of Congress.

religious authorities everywhere and sustaining themselves, more often than not, as much by communal rhythmic exercises as by words or ideas.

Bonding Communities and Combatants

The role of dance and song in disturbing established religious routine and ritual is second only to its importance in sustaining local village and migratory communities throughout human history. Perhaps it is worth pointing out that such sects flourished most vehemently when substantial numbers of persons

found themselves unable to live satisfactory lives in traditional ways in local communities because of overpopulation or some other obstacle. Sometimes, as happened among the bands of prophets in ancient Israel and among sixteenth- and seventeenth-century Protestants in parts of Europe and America, religious protest precipitated new and successful institutional adjustments. More often, sects decayed from within when expectations were disappointed, and/or forcible repression dispersed their followers.

Armies rivaled religious sects in relying on rhythmic exercises to influence human behavior. Infantry soldiers trained to march together in time and

Two European peasant couples enjoy dancing.

reinforce muscular bonding by shout and song were capable of maintaining a solid shield front in battle and could overwhelm less-organized enemies with comparative ease. The earliest known evidence of such tactics comes from Lagash in Sumer about 2450 BCE, in the form of a stone carving showing armored spearmen marching in step behind their commander. Early Chinese warfare also relied mainly on infantrymen who maneuvered in unison to drumbeat.

After about 750 BCE, however, when cavalymen learned to shoot arrows from horseback, faster moving horsemen could outflank infantry and attack with arrows from a safe distance. Accordingly, wherever steppe cavalry raiders were the main threat, civilized armies of Eurasia de-emphasized infantry, put foot soldiers behind walls, and let military drill decay.

In Greece and Rome, however, where steppe raiders seldom penetrated, drill and dance became essential elements of military training after about 650 BCE; citizen armies, marching together and keeping time by shouting, dominated Europe's Mediterranean battlefields for several hundred years thereafter. As a result, intense commitment by ordinary farmers to public affairs and war went along with citizenship in ancient Greece and republican Rome, providing a model for modern democracies when they arose in Europe and America in the eighteenth century. Emotional responses to keeping together in time undergirded and made such behavior possible.

Elsewhere in the world, war and dancing were intimately connected. Among Amerindians, Polynesians, Africans, and others, warriors prepared for battle by

dancing together ahead of time. Such behavior presumably consolidated fellow feeling and assured better cooperation even when the combatants did not array themselves in fixed ranks or learn to maneuver together. Horses cannot keep time, of course, so cavalry was different. Drill was ineffective, and whatever control commanders were able to exert over attacking cavalymen was more by personal example than through prearranged formations.

In the sixteenth and seventeenth centuries both Chinese and European and generals discovered that pikes, crossbows, and handguns, wielded by well-drilled infantry units, could withstand and repel cavalry charges. This altered long-standing military balances within Eurasia, making the superior numbers of civilized armies effective against steppe horsemen as never before. China and Russia were the principal beneficiaries, and by 1757 the last steppe nomad confederacy was reduced to dependence as their expanding Imperial frontiers came together. Almost simultaneously British, French, and Dutch agents established extensive overseas empires in Asia and eventually in Africa as well, thanks to victories won by surprisingly small, well-drilled forces, fruited in large part among local populations, and obeying European commanders. The psychological effect of drill was never more clearly demonstrated than when Indian, African, and Indonesian recruits, moving together in unison, learned to obey European commanders. Older social ties were almost wholly superseded among them by a new collective solidarity that made men of diverse backgrounds into obedient instruments of utterly alien European intruders.

Meanwhile, similar armies, recruited from city slums and impoverished rural communities, strengthened European governments at home, sustaining the aristocratic and privileged urban classes of Europe's old regime.

The French Revolution and the Napoleonic wars of 1789–1815 expanded the role of army drill among Europeans, creating citizen armies on the model of the Roman republic. The French example proved contagious, so by 1914 almost all European governments drafted young men for a year or more of military

training and assigned them to reserve units throughout their active years. Such military training involved long hours of drill and patriotic exhortation that proved very effective in superseding village ties with new national identities. Accordingly, during World War I, national rivalries sustained mass armies, numbering in the millions, through four years of military stalemate, before ending with the sudden collapse of Germany and its allies when hastily trained American soldiers arrived on the Western Front to reinforce the flagging French and British. World War II (1939–1945) turned into an even more destructive disaster for Europe and transformed Asia and Africa by making European empires unsustainable. In every theater of war the power of drill to create obedient soldiers manifested itself, and as Asians, Africans, and Americans began to participate actively in the two World Wars, new national identities took hold among them, thus ending Europe's temporary dominance. Economic and demographic changes worked along parallel lines; but military drill among Asians, Africans, and Americans was what triggered this worldwide shift of power.

A Tool for Society

Among many peoples, dance has never been restricted to religious and military affairs. Urban populations were too large and diverse to dance together, as villagers continued to do, but subgroups could and did dance privately among themselves. Dancing perhaps always played a role in selecting mates and continued to do so in urban settings. In Renaissance Italy, for example, dancing among the urban upper classes became a way of showing off fine clothes, good manners, and sexual attractiveness. This Italian style of ballroom dancing then spread across northern Europe in early modern times. In addition, dancing could express and exhibit the grandeur of a king, as Louis XIV of France (reigned 1643–1715) well knew. As a youth he participated personally in exhibitionistic dances; then he settled for watching as professional dancers developed the art that today is known as ballet.

As for public affairs, after the French Revolution, marching and rhythmic shouting became important

ways of political mobilization. German and Czech nationalists used gymnastic exercises, for example, to foster new sentiments by coordinating muscular movements among hundreds or thousands of participants. Marxists soon followed suit, when the Viennese socialist Victor Adler modeled annual May Day parades on traditional Catholic Corpus Christi Day processions; other Marxists elsewhere imitated this event, as Stalin's May Day parades in Moscow illustrated. Massive gymnastic exercises took especially strong root among Chinese and Korean Marxists, where Buddhist sects had prepared the way for muscular demonstration of their new, secular sort of religion. Meanwhile in Austria, the youthful Adolf Hitler, repelled and fascinated by watching the Marxists' May Day parade, subsequently used marching, uniformed party members to reclaim the streets of Germany and Austria for the Nazi party that he created. Unquestionably, the popular, emotional support these and other political parties and revolutionary governments attained in the twentieth century rested largely on muscular bonding aroused by march, song, and dance. Restless and rootless young men were especially attracted to such behavior, and everywhere remain an especially volatile element in human society.

Political parties and movements in more stable civil societies, like the United States, also resort to marching and rhythmic chanting on occasions of unusual excitement, like election rallies. More surprising was the dismantlement of apartheid in South Africa, accomplished after 1990 by dancing urban crowds of Africans, who drew directly on village customs of community dancing. Less well coordinated rhythmic muscular protest also sustained the agitation in Teheran that brought Ayatollah Khomeini to power in 1979; and the collapse of Communism in Russia in 1990–1991 also provoked improvised rhythmic crowd behavior in the streets and squares of Moscow. Sporadic and more or less spontaneous movement together in time may also be observed among crowds attending athletic events throughout the world.

Obviously, our capacity for arousing common feeling by dancing, shouting, and marching together

is as varied and vigorous as ever. It is sure to persist, and seems likely to remain politically and religiously important in times of crisis, even though older, localized community-wide dancing on festival occasions is in general decay and may eventually vanish.

Daoism

Daoism is a philosophy that focuses on self-cultivation and finding value and purpose in this life. It developed into a philosophy of nature, a political philosophy, and a religion that has had a profound impact on cultural, social, and religious life in China. While Daoism changed and developed from its early days before the common era and throughout the centuries—and spread worldwide—it maintained its original position as the Way (*dao*) of conducting human life.

One of the Three Teachings (*sanjiao*) of China (the others being Confucianism and Buddhism), Daoism is perhaps the most difficult to define. Strictly, Daoism is a religio-philosophical system developed during the Warring States period (475–221 BCE); broadly characterized, it is simultaneously an attitude toward life and a soteriological (salvation-oriented) tradition based on harmony with the *dao* (the Way), the immanent source of all existence and the path it lays for humans to follow. Daoism encompasses often-contradictory beliefs and practices, such as shamanism, alchemy, and martial arts. Traditionally, scholars distinguish between an original Daoist philosophy and a later Daoist religion, the former given greater legitimacy than the “superstitions” of the latter. More recently, this division has been challenged, and the development of Daoism is now described as a cumulative process integrating commonly held teachings and fundamental notions, particularly the unity of man and the natural order. The integrative character of Daoism and the unofficial nature of many of its sects make current estimates of its worldwide membership range widely, from 20 million to 55 million.

Most Daoist concepts come from Daoism’s foundational book, the *Daodejing* (Classic of the Way and Its Power). Although more likely a compilation developed over centuries and only finalized in the third century BCE, it has traditionally been attributed to Laozi (sixth century BCE), an archivist at the Zhou court. According to China’s first universal history (second century BCE), after observing the dynasty’s decline, Laozi headed west. Before leaving the empire, he was convinced to record his precepts. Only five thousand characters in length and divided into two parts, the *Daodejing* lays out Laozi’s definition of *dao* and his prescription for a “right” society in accord with it. It is a series of cryptic, short teachings, meant as a handbook for rulers in the art of governing in harmony with the universal order. Laozi’s teachings were expanded by Zhuangzi in an eponymously titled book (c. 330 BCE) that first presents Daoism as a philosophy for ordinary individuals. Using parables to demonstrate the relativity of all knowledge and values, the *Zhuangzi* levels social difference and, in contrast to Laozi’s writings, rejects all participation in society. It harks to a primitivist society where, free from the ethical dangers of the world, ultimate harmony with nature can be achieved. Together, the *Daodejing* and *Zhuangzi* outline Daoism as a metaphysical rather than human-centered philosophy, in which the ultimate end is *wu* (nonbeing), an emptiness through which *dao* can work unimpeded.

As a philosophy of life, Daoism is ingrained in Chinese culture, bridging the more rational Confucianism and the more metaphysical Buddhism. Daoism’s influence is clear in Chinese science and medical knowledge, which draw on its emphasis on

I realized that Eastern thought had somewhat more compassion for all living things. Man was a form of life that in another reincarnation might possibly be a horsefly or a bird of paradise or a deer. So a man of such a faith, looking at animals, might be looking at old friends or ancestors. In the East the wilderness has no evil connotation; it is thought of as an expression of the unity and harmony of the universe. • William O. Douglas (1898–1980)

harmony with nature and its practitioners' belief that to understand nature is to glean insight into the universal order. Daoism has also shaped Chinese literary and aesthetic sensibilities. Its ideas have been acculturated into other Asian cultures, particularly those of Japan, Korea, and Taiwan, where they have influenced autochthonous traditions. It has also become influential in the West, offering an alternative spirituality through practices like *taijiquan* (tai chi) and feng shui.

Daoism and Chinese Syncretism

Though the division into the Three Teachings is practical for appreciating the differences between Confucianism, Buddhism, and Daoism, the boundaries between them have never been sharply drawn. Rather, they are seen as complementary, pointing to the same goals: humankind's full possession of its humanness and its immortality through harmony with *dao*. The Chinese share singular conceptions, most clearly that of *dao*, which means "road" or "way," though it is also understood as "way to follow" or "rule of conduct." The fluidity of the term allows for each of the Three Teachings to nuance its definition. The concept, however, shares a common cosmology, which describes the universe as a hierarchically organized mechanism in which the parts correspond to the whole. The world is divided into three spheres (heaven, Earth, and human), each with its own *dao*, mirroring one another in a macrocosm–microcosm relationship. Communication and harmony between these spheres is crucial to maintain a universal order constantly under threat. Chinese thinkers also see the natural order as manifested in simultaneously antithetical and complementary aspects, known as yin and yang, each of which cannot be defined without the other. Yin and yang encapsulate

the relativity of all things, because any one thing can be either yin or yang in relation to another.

The complementarity of the Three Teachings' foundational concepts is made apparent by efforts throughout Chinese history to integrate the Teachings into a single movement. But this complementarity must not be overstated; deep-seated rivalries for influence at court and over the masses existed among Confucians, Daoists, and Buddhists. Their differences were more than political; while sharing basic concepts, each adopted a distinct attitude toward life, society, and nature. Confucianism, for example, concentrates on creating an ethico-political system to shape a "right" society through propriety. Buddhism abjures Confucian social values, while espousing beliefs, like the illusory nature of the physical world, diametrically opposed to Daoist doctrine. For its part, Daoism represents a more personal and spontaneous approach to life than Confucianism, and a metaphysics more firmly grounded in nature than Buddhism. It builds upon collective concepts, elaborating them into a distinct "way."

Basic Concepts of Daoism

Dao, as defined by Laozi, is a metaphysical principle, both the ultimate order of the cosmos and the source from which everything emanates. The term itself is a mere approximation, as Laozi admits: "I do not

know its name; I call it the Way. If forced to define it, I shall call it supreme" (*Daodejing* chapter 25; these and subsequent quotations are from the Beck translation).

Although the term was originally used to convey an object's place in a hierarchical order, *dao* itself is outside that order. Not a creator, it is nonetheless the origin of all things in the hierarchy. For example, *dao* is not God (*ti*), but God originates in *dao*. One of its essential attributes is spontaneity. Although it is the ordering principle of the universe, "the Way

never interferes, yet through it everything is done” (chapter 37).

Closely related to *dao* is the concept of *de*. Usually translated as “power,” *de* refers to the Way’s efficacy in the realm of the tangible. *De* is also “virtue,” not moral action but the power that the Daoist acquires by living in harmony with the universal order. Daoists approach *de* in three distinct ways: one aims, through meditation, at the conservation of the *dao*’s power as it flows through the body; the second, in contrast, seeks to increase *de* through various programs of movement, such as *taiqijuan* or kung fu exercises, which unblock the *qi* (life force or breath) and rejuvenate the body; the last offers the help of priests in managing *de*, because Daoist practices are efficacious only if consistently performed. Thus, Daoist priests, who understand the flow of *qi*, help the untrained to unblock its flow.

In the concept of *de* we see the interaction between *dao* and man. As a microcosm of the universal order, the body mirrors the plan of the cosmos; and the same forces flow through both. To Daoists, the metaphysics of *dao* and *de* explain and shape human ethics. The ethical ideal of Daoism is self-suppression—*wu*, or inner emptiness. As there is no thing other than emptiness at the core of the Way, so it should be in the human mind. One should be moved by instinct, not rational thought, like a child, embracing the spontaneity inherent in *dao*. *Wu* is outwardly manifested in *wu wei*, or nonaction, a concept that refers not to absolute inaction but to the absence of self-determined action for particular ends. Daoists use the metaphor of a river, malleable yet powerful enough to erode rocks, to explain the above. *Wu wei* is intrinsically tied to the concept of yin and yang, which makes it intelligible: since each action inevitably leads to its opposite, every deliberate intervention ends in failure. In contrast, nonaction leads to success. Even in following the Way, people should not consciously endeavor to do so, for striving results in straying from *dao*.

Daoists seek a return to a past prior to the corruption of civilization, advocating a primitivist society that follows the rhythms of nature. According to

In celebration of the New Year, Chinese display the Lantern Pagoda. Hung with fifty individual lanterns it honors various gods and brings light, a symbol of prosperity.

Daoists, the unity of the universal order has declined since the golden age, a fact elucidated by the short life span of man, who in the past supposedly lived hundreds of years. Zhuangzi explains that, attempting to stem the decline, rulers unsuccessfully interfered with the flow of *dao*, resulting in defiled purity and a useless search for knowledge. Two main doctrines follow: the espousal of laissez-faire government and the rejection of education. Laozi most clearly elucidates Daoist social ideals: “the more restrictions there are, the poorer the people; . . . the more clever cunning, the more contrivances. . . . Do not interfere, and people transform themselves. . . . Do not intervene, and people prosper” (chapter 57). The king’s *wu wei* must extend to the rejection of education. Laozi condemns even the desire for knowledge, because it leads to competition over status and profit. The ideal society has neither schools nor books; its people are simple in their true nature. Zhuangzi goes further: law and virtue must be excised, since good and evil, inevitably reverting to each other, are relative concepts. This

relativity points to an emerging Daoist skepticism and leveling of moral distinction.

Historical Development

Daoism originated from the shamanic practices of the third millennium BCE. Exhibiting themes such as the search for harmony and immortality, in the first millennium BCE shamanism became associated with the *fangshi*, respected healers and diviners. During this period, Laozi's mystical politics and anarchic ideals also developed, together with Zhuangzi's emphasis on subjectivity and disregard for external behaviors. During the Qin and Han dynasties (221–206 BCE; 206 BCE–220 CE), the Huang-Lao masters, adherents of Laozi's precepts and his ideal government, gained influence at court. Although the emperor Han Wudi (156–87/86 BCE) established Confucianism as the state's official doctrine, rulers privately practiced Daoism, seeking to emulate the semimythical Yellow Emperor.

Emergence of Religious Daoism

During the first century BCE, a messianic Daoism developed that was utopian in outlook and aimed at establishing an era of "great peace." It inspired the Rebellion of the Yellow Turbans (184 CE), who sought to overthrow the Han dynasty. Although the rebellion was defeated, messianic tendencies remained within Daoism. The second century CE saw the emergence of religious Daoism in a new organization that brought temporal and spiritual powers together under the control of the Tianshi (Celestial Masters). In 142 CE, the now-deified Laozi is said to have given Zhang Daoling the definitive, "orthodox" doctrine to replace people's contemporary religious practices. The doctrine sought, through rituals like confession, to expiate sins that resulted in disease. In 215 the Celestial Masters sect was constrained to submit to Cao Cao, founder of the Wei dynasty during the Three Kingdoms period (220–265 CE). The result was the official recognition of the Celestial Masters, who helped legitimize both the Wei and the succeeding Western Qin dynasty (265–316 CE).

The fall of the Western Qin to northern barbarians led to a migration southward, where the Wu dynasty (222–280 CE) arose. In the period of the Southern Dynasties, Daoism was influenced by the traditions of the lower Yangzi (Chang) River, particularly the belief in *zhenren*, pure immortals immune to the world's decay. The immortals became models of attained agelessness, the realization of which was seen as possible through alchemy and magic. By the fourth century CE, this synthesis of the Daoism of the Celestial Masters and preoccupation with immortality led to the development of a competing sect, the Mao Shan school. In general, Daoism gained official support but not sole recognition in the South, while in the North it became the official religion of the Northern Wei dynasty (386–534), whose rulers claimed to be deputies of Lord Lao.

Daoism from the Seventh Century

Daoism's greatest success came with the reunification of China under the Tang dynasty (618–907 CE), as it spread throughout the empire. The founder of the dynasty was believed to be Laozi's messianic descendant, a notion which became part of official state ideology. Numerous temples and monasteries were built, and the *Daodejing* joined the Confucian classics as part of the civil-service exam. During this time, Daoist scriptures also attracted the attention of foreign rulers and were translated into other languages. During the Song dynasty (960–1279), the Daoist canon was expanded and printed for the first time. However, with the decline of the first (Northern) portion of Song dynasty (1126), Daoism lost its place as the official religion. In the fray, several new sects developed. Of these, the Zhuangzhen (Complete Perfection) sect, noted for its ethical teachings, gained the favor of the Mongols and was thus able to challenge the Celestial Masters' preeminence. The sect's emphasis on asceticism and hygienic techniques to prolong life became one of the most important and prevailing currents in Daoism.

During the Yuan dynasty (1279–1368), Daoists used their prominence in the north to lead a

persecution against Buddhism, hoping to diminish its growing influence. However, the tide turned, culminating in the state-sanctioned burning of Daoist apocrypha in 1281. In the south, meanwhile, the Celestial Masters' influence continued unabated, although challenged by newly developing currents in Daoism. These new currents embraced Neo-Confucian beliefs, which gained them the support of conservative officials and intellectuals.

During the Ming dynasty (1368–1644), the elite became estranged from Daoism, and Daoism's social status dwindled. The Ming elite held double standards in respect to Daoism: they still drew on its notions to justify their rule, but they put the religion under strict control, inhibiting its independent development. Stifled by the ruling class, Daoism flourished among underground religious sects. The rulers of the Qing dynasty (1644–1911/12) saw Daoism as potentially seditious and started to suppress it, withdrawing most of its privileges. The religion continued to develop among minorities and the lower classes however.

Spread and Influence

With the exception of Taiwan, which saw an influx of Daoists in the seventeenth and eighteenth centuries as part of mass migrations from Fujian Province in the southern mainland, Daoism has not spread systematically to other areas of the world. Its doctrines and practices, however, were absorbed into local traditions across East Asia and are now making inroads in the West. The seeming lack of an exclusive mythology, historical contexts, and personal references in Daoist scriptures has helped give them universal appeal.

Korea and Japan

Daoism arrived in the Korean Peninsula in 624 CE, when it was at its height at the Tang court. The emperor sent emissaries bearing the *Daodejing* and *Zhuangzi* to the three Korean kingdoms, two of which fully welcomed their teachings. In the kingdom of

Koguryo, Daoist priests' influence was such that many local Buddhist temples were made Daoist. The kingdom of Shilla sent scholars to China to learn more about the religion and included the *Daodejing* in the Shilla civil-service exam. Although a Daoism stressing self-discipline was popularized at all levels of Korean society, by the fourteenth century Daoism was in decline as Buddhism resurged. Further suppression came with the Japanese invasion of 1592, after which the vitality of Daoism as an independent religion faded. Yet Daoism's influence in Korea is evident in traditional gardening and in the country's flag, the central symbol of which is the Taeguk, representing the correspondence between heaven and Earth.

The Japanese first encountered Daoism in the seventh century CE. Early on, Daoism's affinities with the animism of Japanese Shinto eased an acculturation of Daoist doctrines into Shinto traditions. The introduction of specific Daoist practices dates to the Heian period (794–1185), when Masters of Yin and Yang—diviners learned in the occult—gained influence at court. In the eighth and ninth centuries, practitioners of Shingon Buddhism adopted Daoist physiological practices and the belief in the immortals. Tendai Buddhists embraced Daoist magical arts and techniques for prolonging life. Daoist mysticism made its strongest inroads in Japan through its influence on the Zen schools of Rinzai and Soto, which were introduced from China in the twelfth and thirteenth centuries and are still active today.

Daoism in the West

Western opinions of Daoism have changed from the days when the Italian Jesuit Matteo Ricci first visited China in 1582. Seeing Daoism as an obstacle to the spread of Christianity, Ricci allied himself with court Confucianism and decried Daoism as perverted paganism. This negative attitude persisted into the nineteenth century, when philosophers such as G. W. F. Hegel deemed it a throwback to philosophy's infancy. However, popular nineteenth- and early twentieth-century writers such as Leo Tolstoy and

Franz Kafka brought it to a broader audience, while thinkers such as the philosopher Martin Heidegger and the psychologist Karl Jung embraced its tenets as confirmation of their own subjective philosophies.

The Western interest in comparative studies has brought Daoism to the forefront. Daoist theories have infiltrated discussions of scientific subjects, while its doctrines serve environmentalists as an alternative philosophy with which to criticize Western attitudes toward nature. Daoism's questioning of traditional authority and the substantial presence of women in institutionalized practice have also made it appealing to certain strands of feminism, which see in the interdependence of yin and yang a less divisive way to conceptualize gender. Daoism has also attracted attention at the popular level, its prescription for a simplified life appealing to those who seek to lessen the effects of technological dependence. For example, feng shui is used as a means to harmonize urban living with the energies of nature.

Daoism Today

With over eighty-six sects worldwide, Daoism is one of five sanctioned religions in the People's Republic of China—the others being Buddhism, Islam, Protestantism, and Catholicism. However, its relationship with the government is uncertain at best, since only two sects are officially recognized: the school of Complete Perfection and that of the Celestial Masters. Although the greatest number of Daoists live in China, Taiwan is the center of official modern Daoism and has been since 1949, when the sixty-third Celestial Master, Zhang En Pu, took refuge there. With millions of adherents practicing *taijiquan*, visiting Daoist temples, and studying Daoist healing methods both on Taiwan and on the mainland, the ultimate influence of Daoism in modern Chinese culture is unmistakable.

As naturalist aboard the *HMS Beagle*, Charles Darwin closely observed various species. In 1859, his book *On the Origin of Species* was published, which explained how the struggle for survival would naturally tend to select traits that gave a competitive advantage. This theory of evolution by natural selection was accepted by the scientific community but refuted by the Christian clergy.

Charles Robert Darwin was born in Shrewsbury, England, on 12 February 1809, the son of the physician Robert Darwin and Susannah Wedgwood Darwin, of the Wedgwood pottery dynasty. Charles started work on a medical degree at Edinburgh University but, repelled by the sight of surgery performed without anesthetic, did not finish his studies. He later went to Cambridge University in preparation for becoming a clergyman in the Church of England.

In 1831 he took the post of “naturalist” aboard the *HMS Beagle*, under the command of Captain (later Admiral) Robert Fitzroy (1805–1865), on its surveying voyage to South America and the Pacific and Indian Oceans. On his return Darwin published an account of the journey, as the third volume of Fitzroy’s *Narrative of the Surveying Voyages of the Adventure and Beagle* (1839). Over the next four years he oversaw the publication of various reports, by experts of the day, on the mammal, bird, fish, and reptile specimens he had collected. He also wrote an important book on coral reefs and several monographs on fossil and living barnacles. When his travelogue was reissued in an enlarged edition as the *Journal of Researches into the Natural History and Geology of the Countries Visited during the Voyage of H.M.S. Beagle*

Round the World (1845), he received more widespread and popular acclaim.

Darwin had long pondered the variety of life. He was influenced by the geologist Charles Lyell (1797–1875), who outlined the idea that geological changes to the Earth had happened over millions of years, rather than the thousands of years deduced from the biblical account of Genesis and the great flood. The economist Thomas Malthus (1766–1834) had also written an influential book, *An Essay on the*

Charles Robert Darwin (1809–1882), biologist. Photo by Ernest Edwards. Smithsonian Institution.

It is not the strongest of the species that survive, nor the most intelligent, but the one most responsive to change. • Charles Darwin (1809–1882)

"The Tree of Life," drawn by Charles Darwin between 1837 and 1838. The text reads, in part: "Case must be that one generation then should be as many living as now. To do this & to have many species in same genus (as is) requires extinction." Cambridge University Library.

Principle of Population (1798), in which he argued that the population of the Earth could not expand forever and that at some point starvation, disease, pestilence, war, and other "natural" causes would prevent further increase.

During his travels, famously including those through the Galápagos Islands, Darwin had regularly come across unusual groups of very closely related

species, which he likened to variations on a theme. Meanwhile through his gentlemanly pursuits, he had come across bird, dog, and horse breeders who had created new breeds that differed from one another as much as wild species might differ from each other. These discoveries stimulated Darwin to construct his theory of evolution by natural selection.

Darwin had been working on a manuscript for many years when, in June 1858, he received an essay from a fellow world traveler and naturalist, Alfred Russell Wallace (1823–1913). Wallace had independently arrived at exactly the same conclusion as Darwin: that the vast reproductive ability of living organisms, subtle variation within species, and the struggle for survival would result in the selection of any slight advantage and the inheritance of that advantage in future offspring.

Darwin was a famous naturalist while Wallace was younger and less well known, but Darwin knew he would have to publish or forfeit credit for the originality of his ideas. Through the support of his close colleagues Charles Lyell and the botanist Joseph Hooker (1817–1911), Darwin and Wallace presented a joint paper to the Linnean Society of London on 1 July 1858, and a year later Darwin's most famous book, *On the Origin of Species*, was published.

The book soon generated a storm of controversy. At the beginning of the nineteenth century, the study of natural science was intricately intertwined with an appreciation of the wonders of God's creation—many of the most important naturalists of the day were clergymen. It was assumed that species were fixed, created by a divine hand and therefore immutable.

With Darwin and Wallace came, for the first time, an explanation of how species might change—an explanation that was coherent, plausible, and readily acceptable to the scientific community. It was not, however, acceptable to the clergy. They took Darwin's book to suggest that the world had not, after all, been created in a week, that humankind had not been created in God's image but had begun as something more primitive. To them, Darwin's

book reduced the story of Creation, and of Adam and Eve, to a myth.

Darwin died in 1882, without any formal state honor or recognition. Today, however, Darwin is recognized as one of the most important figures in the history of science and, with Wallace, is credited with producing the theory that still underlies all of biological science. Every aspect of the study of living things, from ecology to genetics, is underpinned by their original concept of evolution by natural selection.

Dating Methods, Archeological and Historical

Techniques for determining the ages of objects at archaeological sites are critical to understanding the evolution of human societies. Archaeologists use relative dating methods (such as a fossil's position within layers of soil), to determine the sequence of events and absolute dating methods (such as the radioactive decay of a carbon isotope), to determine the actual age of an artifact.

Archaeologists employ a broad array of techniques collectively called dating methods to determine when “things happened” in history. These methods are applied directly to objects in order to determine their actual age or to situate them accurately in a chronological sequence. The dates on individual items may then be associated with and applied to the archaeological sites from which they were recovered. By a further extrapolation, the dates of these sites are then used to answer general questions concerning the timing and tempo of significant events or developments in the history of humanity: the evolution of upright walking, the earliest tool making, the controlled use of fire, humanity's geographic expansion beyond its African evolutionary nursery, the origins of agriculture, the development of metallurgy, the invention of writing, the appearance of urban civilizations. Our understanding of the origins of these and myriad other important steps in the evolution of human societies often is based, ultimately, on our ability to accurately and precisely date objects associated with these developments.

Dating methods employed in archaeological analysis can be divided into two general categories: relative methods and absolute (sometimes called

chronometric) procedures. Relative dating involves placing objects, sites, or events in a chronological sequence, without reference to an actual date, year, or even to a broad range of years. Absolute dating techniques produce actual dates or age ranges.

Relative Dating Methods

Among the relative dating procedures employed by archaeologists, the ones most commonly used involve sequencing objects, occupations, and sites on the basis of the soil levels in which cultural remains have been found.

As long ago as the late eighteenth century, the British geologist William Smith recognized that Earth's history is written as a metaphorical book whose pages are represented as a series of soil layers, one laid down upon another in a sequence across a vast expanse of time. Smith's analysis of these layers—the stratigraphy of buried geological deposits—provided scientists with a sequential natural history in which each layer contained fossil evidence of the types of life forms that dominated during the period in which the layer was deposited.

Archaeologists soon realized that stratigraphic analysis could similarly be applied to human history. Human-made objects and the remains of other materials whose context in the soil was the result of human activity were, like fossils of plants and animals, deposited in soil layers being laid down during the period in which those objects were lost, discarded, or deposited for safekeeping. Archaeologists recognized that cultural materials, like fossils, could themselves be sequenced on the basis of their relative position in a succession of strata.

Hugues Fourau, *Portrait of English Geologist William Smith*. Smith's groundbreaking work encouraged archaeologists to apply stratigraphic analyses to human history.

Further, because human activity itself can produce layers of deposit, cultural stratigraphy can be read to determine a relative chronological sequence of occupations of the same spot. For example, so-called tells in the Middle East are artificial hills produced by the frequent reoccupation by human beings of the same locations. Each occupation results in the deposition of materials lost and discarded and, in so doing, contributes to the formation of the mound, with the materials left behind by each subsequent occupation located on top of previous deposits. For example, the tell of Hazor (Tel Hazor) in Israel is an artificial hill produced by the remnants of some twenty-one separate occupations of the same location, with the remains of each successive occupation overlying each previous one.

Absolute Dating Methods

In most cases, the application of a relative dating procedure like stratigraphic analysis represents a preliminary step in archaeological dating. The hope always is to go beyond merely sequencing and to determine

a site's age in a chronometric sense. One of the most important chronometric procedures archaeologists employ is radiocarbon dating (also called carbon dating or C-14 dating), one of a series of so-called radiometric techniques. Radiometric dating methods, including carbon dating, potassium-argon dating, argon-argon dating, and uranium-series dating all rely on the existence of what amounts to natural clocks or calendars in archaeological and geological specimens. These natural calendars are produced by the fixed and measurable pace of the decay of radioactive (unstable) isotopes (varieties) of elements that occurs naturally in raw materials used by ancient human beings.

Radiocarbon Dating

In 1946, the University of Chicago chemist Willard Libby predicted the existence of carbon 14 in living matter, and by 1949 he had measured contemporary levels of this unstable variety of carbon and assessed its half-life—in essence he began the process of calibrating this natural clock. Soon thereafter, he began to apply the method to dating archaeological specimens. With radiocarbon dating, the known rate of decay of a radioactive variety of carbon, called C-14 (carbon 14) for the fourteen particles (six protons and eight neutrons) in its nucleus (as compared to the twelve particles—six protons and six neutrons—present in the stable and abundant variety of carbon), provides the archaeologist with a natural calendar.

Just like carbon 12, carbon 14 combines with oxygen in the atmosphere to produce carbon dioxide. Plants respire—in essence, they breathe—and, through photosynthesis, break apart the bonds between the carbon and oxygen atoms in carbon dioxide. Plants exhale the oxygen and retain the carbon, from which they manufacture their leaves, stems, roots, fruits, bark, and so forth. Carbon 14 is incorporated into plant materials in the same proportion as it appears in the atmosphere. When animals ingest plant materials, their bodies use the ingested carbon in the plant to produce bone, muscle, sinew, and so on, and the carbon 14 provided by the plant is

incorporated into the animal's body in the same proportion as was present in the plant. When a carnivore eats a plant-eating animal, it incorporates carbon 14 into its body in the same proportion as was present in its prey. In this way, all living things, as long as they are alive, breathing, and eating, are in radiocarbon equilibrium with the atmosphere.

Because carbon 14 is unstable, it constantly undergoes radioactive decay at a steady and measurable rate. Radioactive decay rates are expressed as half-lives, the length of time it takes for half of the radioactive material present in a substance to decay to a stable form. The half-life of carbon 14 has been measured at 5,730 years.

As long as an organism is alive, the carbon 14 that is slowly disappearing through that process of decay is immediately replenished (by plants as they breathe and by animals as they eat). Death breaks that cycle. After death, the decaying carbon 14 is no longer replenished, and its loss becomes calculable. It is the constant, steady, and measurable decay of carbon 14 that provides a natural chronometer in substances containing carbon—essentially, anything that was once alive.

Scientists can precisely calculate the amount of carbon present in a specimen about to be dated; they also know how much carbon 14 would be present in the material if it were entirely modern—in other words, if it were alive today. If the amount actually present in the object is less than would be expected in a modern material, the amount of time it must have taken for the proportion of C-14 to decline to its current measure can be calculated, providing an age for the material.

Radiocarbon dating, by its nature, can be applied only to organic materials, such as bone, wood, charcoal, seeds, fruit pits, roots, hair, and hide. The half-life of radiocarbon also places restrictions on the application of carbon dating. Any specimen less than a few hundred years old usually is too young to date, as not enough of the radioactive isotope has decayed for an accurate age determination. In its current application, any specimen much older than about seven half-lives (approximately forty thousand years) has so

little of its original carbon 14 remaining that dating accuracy diminishes dramatically, and the technique becomes unreliable. Ways of extending the outer boundary of radiocarbon dating to fifty- or even sixty-thousand years are currently being developed.

Finally, it should be added that the accuracy of carbon dating depends on there being a constant amount of carbon 14 in Earth's atmosphere through time. This turns out not to be precisely the case. Adjusting for this depends on another dating procedure—dendrochronology—which permits carbon dates to be calibrated and better reflect the actual age of an object.

Other methods based on radioactive decay are employed by archaeologists. Perhaps the most important is the potassium-argon technique (a more accurate version of the method is called the argon-argon method) in which argon-gas buildup is measured in volcanic rock (the gas results from the decay of radioactive potassium). The argon gas accumulates at a known rate, and therefore the age of the volcanic rock (meaning when the molten material solidified) can be determined. This technique is applicable to material millions and even billions of years old and so is most useful in dating the very ancient sites of our human ancestors. In one of its most interesting applications, the volcanic ash in which ancient human ancestors left their very modern-looking footprints at Laetoli, in Kenya, has been directly dated to about 3.5 million years ago.

Radiation Damage Techniques

Another class of radiometric techniques relies on the statistically predictable nature of radioactive decay in an indirect way. These procedures fall into a subcategory of radiometric dating called radiation damage techniques. These techniques, which first were used in the 1950s, take advantage of the fact that radioactive decay may leave measurable damage on archaeological specimens, damage that accumulates regularly through time. The amount of damage, therefore, is proportional to the amount of time that has passed. For example, the fired clay in a ceramic

object deposited in the ground is buffeted by radioactive decay that originates in the surrounding soil. The energy released through that decay is captured by the ceramic object, trapped in its atomic lattice in an amount proportional to the amount of time the object has been in the soil. This trapped energy can be released by heat in a procedure called thermoluminescence, or by light in the application called optically stimulated luminescence; the amount of energy released can then be measured. Once the rate at which the radioactive material in the soil is releasing energy—the so-called background radiation—is calibrated, the rate at which energy is trapped by a ceramic buried in that soil can be calculated, and, by inference, the age of the artifact can be determined. Dating techniques based on the rate of energy capture in archaeological materials are applicable to raw materials that possess a structure that, in fact, acts to trap such energy. These materials include ceramics, as well as some minerals, coral, teeth, and shell. Luminescence dating had a wide range of applicability; it has been used successfully to date ceramic objects just a few hundred years old, calcite deposits more than 250,000 years old, and heated flints up to 500,000 years old.

Electron spin resonance, which measures the amount of energy trapped in shells, corals, volcanic rock, and tooth enamel, is another radiation damage technique. Here again, the amount of trapped energy present in an archaeological specimen is a function of time; once the amount of trapped energy is measured and the background radiation calculated, the amount of time since the rock, shell, coral, or tooth formed can be computed. Electron spin resonance has been applied successfully to objects as young as one thousand years and as old as one million years of age.

Fission track dating, a third radiation damage technique, makes use of the fact that radioactive decay may leave discernible, microscopic tracks in a material. These tracks may accumulate at a regular rate through time. When this rate can be estimated and the number of tracks counted, an estimate of the age of an object can be calculated. Fission track dating has been used to date materials as young as a few

thousand years old; from a human standpoint, there is no effective upper limit to the applicability of this procedure.

Dendrochronology

Biology also supplies the archaeologist with an important natural calendar in the form of the annual growth rings of trees. It is commonly the case that trees add a single growth ring for each year that they are alive. In many cases, the thickness of a growth ring is a factor of a measurable aspect of the environment during the year the ring was added; for example, mean temperature or amount of precipitation. This correlation between tree ring width and yearly climate fluctuations actually was recognized in the fifteenth century by Leonardo da Vinci. In the first three decades of the twentieth century, the University of Arizona astronomer A. E. Douglass (1867–1962), attempting to assess a possible correlation between sunspot activity and climate change, examined fluctuating tree ring width and is credited with recognizing the potential of tree ring analysis in archaeological dating. In the American Southwest, where tree ring dating, or dendrochronology, has been particularly useful in archaeological application, the width of an annual tree ring is proportional to the amount of rainfall that fell in the year the ring grew; thick rings are added in years when precipitation is abundant, rings of intermediate width are added when rainfall amounts are intermediate, and thin rings develop during years when rainfall amounts are meager.

This yearly variation in tree ring width allows researchers to extend a tree ring sequence back in time. Dendrochronologists accomplish this by developing what is called a master sequence for a region by beginning with a living tree. That tree, like all trees, exhibits a nonrepeating, more or less random succession of thick, medium, and thin rings reflecting the nonrepeating pattern of high, medium, and low yearly rainfall amounts during its lifetime. This tree's sequence of ring widths will be a close match to that exhibited by all the other trees of the same species growing in the region since they were all subjected to

the same rainfall amounts as these varied from year to year. The living tree anchors the master sequence in time, as the dendrochronologist knows the precise year in which each of its rings were created simply by counting backward from the outermost, most recently grown ring, which represents the current year.

Next the sequences of tree rings exhibited by a number of dead trees are compared with the rings of the living tree in the search for a substantial, matching series of tree ring widths. If the lives of the living and any of the dead trees overlapped in time, their ring width sequences of thick and thin rings will match for that period of overlap. For example, if the succession of varying widths of the innermost ten rings of the living tree match in size and order the outermost ten ring widths of a dead tree, in all likelihood those two trees were both alive during that same ten-year period. Because we know the precise year each of the living tree's rings correspond to, we can now fix the dead tree in time; its final ring was added in the tenth year of the living tree's existence, and we know what year that was. By repeating the same procedure numerous times with successively older trees overlapping in time, dendrochronologists have developed master tree ring width sequences that reach back more than twelve thousand years. The discovery of well-preserved tree ring sequences in ancient Kauri trees excavated in New Zealand may enable the extension of a master sequence for the region where the tree remains were found back to nearly sixty thousand years.

In practice, when an archaeological specimen of wood is found—for example, a log beam in an ancient pueblo or a fragment of log used in a prehistoric palisade—its ring width sequence is examined by computer, and its fit along the master sequence is determined. In that way, the actual year in which the archaeological specimen died or was cut down can be established. If we assume that the log was used soon after it died or was cut, that year can be associated with the archaeological site in which it was found. Different master sequences have been worked out and are constantly being expanded and refined for various reasons all over the world.

Calibrating Radiocarbon Dating

As mentioned previously, the accuracy of radiocarbon dates depends on a constant proportion of radioactive carbon in the Earth's atmosphere, and this, unfortunately, is not always the case. Tree ring dating, along with a number of other methods, can help control for changes in the atmospheric radiocarbon content. Once laid down in a tree, no additional carbon is incorporated into a ring. Therefore, a radiocarbon date determined for a particular tree ring represents the "radiocarbon year" for that ring's "calendar year" as represented on the dendrochronological master sequence. An enormous number of individual tree rings have been radiocarbon dated, and a calibration curve has been developed. Combining dendrochronology with other methods, notably varve analysis (varves are individual strata deposited in lakes on a yearly basis, one varve for each year), the radiocarbon calibration curve now reaches back approximately twenty-six thousand years. This means that within that period, a given radiocarbon date can be accurately adjusted to a more realistic actual or calendar age by reference to that calibration curve.

Dating with Style

New technologies are constantly replacing old ones, and styles come into fashion and then fall out of favor. Most of us are familiar with the progression of technology and the vicissitudes of fashion in our own culture. Most would have no trouble guessing the approximate date of an automobile with lots of chrome and sharp fins (styles popular in the 1950s) or a photograph in a college catalogue showing male students with long hair and faded, torn jeans (the late 1960s and early 1970s). Even a casual examination of the history of the now nearly ubiquitous iPod shows a series of technological and stylistic developments since the MP3 player's introduction in 2001. If you know when Apple introduced subsequent iPods with new technologies (for example, when they replaced the scroll wheel with the touch-sensitive wheel or when they introduced color displays), you

can tell the manufacture date of an iPod just by looking at it.

Archaeologists may accurately determine an ancient artifact's age in much the same way. If a unique style of making spear tips or pottery has previously and consistently been dated to a particular point in time, then when another spear tip or potsherd is found that matches the known object's form and style, archaeologists propose that the newly found artifact dates to a similar period. For example, when confronted with a long, narrow spear point with a shallow channel running up less than half the length of each face of the point, a New World archaeologist will confidently conclude that the spear point in question is between 10,000 and 11,500 years of age. This confidence results from the fact that whenever points looking like that have been found previously, they have been associated with dates in that range (for example, by being found embedded in an animal bone that produced a radiocarbon date that matches that time period).

Other Methods of Dating

There are other dating techniques used by archaeologists. Archaeomagnetic dating is an absolute technique that has been used especially in the American Southwest for more than thirty years. Magnetic particles in, for example, the bricks in an ancient kiln will point to what was magnetic north at the time the kiln was in use. Noting where they point and knowing when that location corresponded to magnetic north allows archaeologists to date the kiln. The Colorado State University scientist Jeff Eighmy and his colleagues

have worked out a master curve of the locations of magnetic north that extends from the present back to approximately 600 CE. Seriation, a relative technique developed in the late nineteenth century, is based on a typical pattern of change in the popularity of artifact styles from their introduction into a culture, through their growth in popularity, to their decline and eventual replacement by new styles.

Whatever the procedure used, accurate sequencing and dating allows the archaeologist and historian to construct a temporal framework from which the trajectory of human cultural development can be calculated. Indeed, being able to answer the question "when?" provides researchers with a context within which the others whys and wherefores of human history can be answered.

Decolonization

The emergence of many independent states from under colonial rule or domination by European powers between 1945 and 1990 was more significant to a large portion of the world's population than the Cold War, yet this decolonization has received less attention from historians. The process led to the sovereign independence of many states in spirit, as well as in name.

Not many years ago decolonization was a Cinderella subject in international relations, the poor sister to the study of the Cold War. For historians, it was the “inevitable” terminus to the history of empire, a sort of punctuation mark before the new history of postcolonial states got under way. In a world in which the division between the communist and noncommunist worlds still seemed the most important issue in world politics, and the great fissure of 1917 the real beginning of modern history, this was perhaps inevitable. Even so, it was always a curiously Atlantic-centered view of the world. It disregarded the fact that for most of the world's peoples, the most important political fact after 1945 was the dismantling of the apparatus of colonial rule or semicolonial domination that had extended over so much of the world, and its replacement by around 150 independent states. There was always a powerful case for saying that the “headline story” of world history between 1945 and 1990 was decolonization.

Toward a Definition

Part of the difficulty, of course, was definition. Like *imperialism*, *decolonization* is a slippery, elusive term that historians and others frequently use without

defining the meaning that they want to attach to it. But to think about decolonization, its significance, and its causes is necessarily to ponder its meaning. We can hardly explain it, or decide when it began, without being sure what it is. Typically it has been used in a narrow and restrictive way to mean the moment at which sovereign independence is granted to a former colonial territory. On occasions, this has been extended to include the process, or series of events, by which independence is reached. In other words, the term has usually been confined to those countries that were formally subordinated to an imperial power (by annexation, settlement, conquest, or protectorate status), and to the political and legal stages whereby they gained sovereignty. Defined in this way, it is easy to see why decolonization has often seemed no more than a brief and predictable epilogue to the age of imperialism.

There are two reasons why this conventional definition is of little use if we want to grasp the real nature of the change that took place. First, it makes no account of those countries where foreign domination in less formal (and less obvious) guise was the dominant fact in their external relations. The list is a long one: it would include China for much of the period from 1842 until 1949; Egypt from 1882 until 1956; Iran from the late nineteenth to the mid-twentieth century; and the “mandate” countries of Syria and Iraq until after 1945. It might include parts of South America between the 1880s and the 1940s, or even later. It ought to include those parts of the former Soviet empire that were complacently regarded by the outside world as willing members of the Soviet Union. In other words, a legalistic definition of *decolonization* drastically reduces the scale of the phenomenon, and

First they ignore you, then they laugh at you, then they fight you, then you win. • Mohandas Gandhi (1869–1948)

Unsigned, *Indian Demons Attacking Fort Defended by European Troops* (c. 1791). After centuries of British dominance, the nationalist movement in India became stronger than anywhere else in the colonial world. Anne S. K. Brown Military Collection at the Brown University Library.

ignores the reality of foreign control in many countries where its overthrow after 1945 (or since 1989) has been the most powerful influence on their international attitudes.

Second, decolonization as the gaining of sovereignty is an unhelpful guide to the substance of freedom and independence. Canada, Australia, New Zealand, and South Africa all received full sovereignty by the Statute of Westminster in 1931. Each

became free to pass its own laws, change its constitution, and conduct its foreign policy. But all remained part of the British Empire and freely accepted the British Crown as head of state. When were they decolonized? Indeed, Australia and New Zealand became more dependent upon Britain for defense than they had been before 1931. Similarly, Egypt was declared independent after the wartime British protectorate was given up in 1922. But no realistic observer would have doubted that the wishes of the British ambassador were a cardinal factor in Egyptian politics.

Decolonization is more usefully thought of as the demolition—slow and gradual in some places, more rapid in others, long delayed in some—of a global regime that had existed in several dimensions since the 1880s, and which had largely disintegrated by 1960. The most obvious aspect of this regime was the partition of large parts of the world into the imperial possessions of the European powers (including Russia) and their junior partners, the United States and Japan. These powers also claimed rights of “informal empire,” through extraterritoriality and “unequal treaties” in theoretically independent states (nineteenth-century China is the best example). They also asserted a legal “norm” that conferred the right to intervene in states whose “standard of civilization” fell below their own—a right usually exercised on behalf of their own citizens. This global regime assumed a division of labor in which imperial states made manufactured goods, or supplied capital, while colonies and semicolonies produced the raw or semifinished commodities with which they were exchanged. Enforced free trade, like that imposed on China by treaty, was the means to achieve this beyond the frontiers of imperial rule. There was a demographic face to this global system. It was the mass emigration of Europeans to places of permanent settlement or (where their numbers were less) social mastery in the extra-European world; and a much-smaller-scale migration of Afro-Asian labor as transients with few rights and little prospect of citizenship in the lands that they settled. Finally,

undergirding the whole was the pervasive notion of a cultural hierarchy (often expressed in terms of “race”). Those cultures not rooted in northwestern Europe might be sighed over for their beauty, admired for their subtlety, or envied for their spiritualism. But they lacked what the late Victorians called social efficiency: the capacity for the “moral and material progress” on which the British rulers of India sent an annual report to the parliament in London.

This broader and more realistic definition may allow us to think more precisely about the causes of the change that decolonization brought. It has become fashionable recently to claim that empire has revived—or perhaps never gone away. But if the criteria above are accepted, it is clear that although empires still exist, and perhaps will always exist in some form, empire as the organizing principle in international affairs, governing the ethos of interstate relations, was a historical phenomenon that gave way around 1960 to a new world order in which its characteristic features were largely obliterated. Indeed one useful way to think about decolonization is to see it as the successor phase in global politics between the end of empire and the onset of the new international conditions that set in after 1990.

Conditions of Decolonization

If decolonization is defined in this way, what were the conditions that brought it about? Typically historians have elected to emphasize one main cause: the irresistible rise of anticolonial nationalism, which forced the imperial powers to abandon their unequal privileges and concede national sovereignty to an emergent group of nationalist politicians. It is possible to find cases where this holds true, but as a general explanation it is defective. It ignores the extent to which, before World War II, colonial rulers had invariably been able to divide or outmaneuver their colonial opponents and keep overall control of the political process. This was what had happened in India, where the nationalist movement was stronger than anywhere else in the colonial world. For colonial

A nineteenth-century print shows native Algerian soldiers in the service of the French Empire, which suffered catastrophic defeat after World War II. Algeria gained full independence in 1962. New York Public Library.

rulers to lose their footing required the intervention of some exogenous force. A second school of historians has seen the decisive change as a loss of interest among the colonial powers, as new domestic priorities (financing the welfare state), new international concerns (the turn toward closer European unity), or more democratic values forced a drastic reappraisal of the imperial “burden.” But this claim is weakened by the fact that after World War II almost all the colonial powers showed a *heightened* interest in the exploitation of their colonial possessions. Third, it is often argued that the rise of the superpowers after 1945 handed global dominance to two states who agreed about little except their opposition to the survival of a Europe-centered colonial order. But this argument, too, must be treated with caution. American attitudes to European colonialism were at best ambivalent before the later 1950s, and superpower dominance before around 1960 is easily exaggerated. It is worth bearing in mind that the smallest

and weakest of Europe's colonial powers, Portugal, did not abandon its colonies until 1974.

The solution is not to retreat into a catchall explanation in which every plausible suspect plays an ill-defined part. What precipitated the fall of the imperial order that had imposed varying degrees of subordination on so much of the world was the astonishing course of World War II, which saw the catastrophic defeat of one of the two greatest colonial powers (France) and the virtual bankruptcy of the other (Britain). It was hardly surprising that the political controls, ideological norms, and economic structures over which they presided, and to whose legitimacy they gave strength, would be drastically if not terminally weakened. The most obvious symptom of this loss of power was the rapid postwar withdrawal of Britain from India, the colony whose military resources had underwritten much of the British imperium in the Afro-Asian world. To all intents, the imperial order was over by 1945. It was rescued by the Cold War, which allowed the old colonial powers, with American help, to recover some of their prewar position, and to offset their losses by accelerating the development of their remaining possessions. But the strain of this effort and the hostility it roused among colonial populations imposed heavy costs, both political and financial. It was aggravated by the partial (but irrecoverable) breakdown of the old order in East and South Asia and the Middle East in the postwar turbulence after 1945. When the superpower rivalry for influence became global in the late 1950s, the remaining apparatus of European colonialism was quickly demolished. By that time, its ideological legitimacy, cultural authority, and economic system had already largely vanished.

Decolonization, then, cannot be reduced to the achievement of sovereignty by former colonial states in a sequence that began in 1947 and was largely completed by the late 1960s. Decolonization was a much larger process that made sovereign independence possible for many small, weak states, and made it much more real than the nominal sovereignty enjoyed by China or Egypt in the interwar years.

Decolonization was a transformation of the international system that occurred under conditions of a gradually intensifying bipolar rivalry. It was slow, untidy, and incomplete—leaving a Portuguese Empire until the mid-1970s, two white minority “settler” states in southern Africa until 1980 and 1994, and a Soviet empire until after 1990. As a phase in world history, decolonization may be considered at an end. Empires will survive (there is a “Chinese Empire” in inner Asia, and a “Russian Empire” in the Caucasus). New empires may appear, not necessarily in the form of territorial dominion. But the Europe-centered world order that decolonization dismantled has gone for good.

Deforestation

Humans have been felling, using, and burning trees for about half a million years, and the forests have receded as human populations have grown and spread. The clearing of woodlands for agriculture has been the leading cause of deforestation, but the harvesting of timber as a raw material and fuel has also played a significant role.

The word *deforestation* is a wide-ranging term to cover the cutting, use, and elimination of trees. Subsumed under it are other activities like fire, domestic heating and cooking, smelting metals, making ceramics, construction of shelter and implements, and the creation of new land for cultivation and grazing. Deforestation is so basic that it is woven into the very fabric of human existence, and hence of world history. Ever since the emergence of *Homo erectus* some 500,000 years ago the quest to provide shelter, food, and warmth has resulted in the use and abuse of the Earth's mantle of forests.

There is much uncertainty about the pace and locale of deforestation during past (and even present) ages. This revolves around the multiple meanings given to three basic questions. What exactly is a forest? What was the extent and density of trees at any past given time? And what constitutes "deforestation"? Pragmatically one may say that a forest can range from a closed-canopy tree cover to a more open woodland, which affects density. *Deforestation* is used loosely to mean any process that modifies the original tree cover, from clear-felling to thinning to occasional fire. It should not be forgotten, however, that forests regrow, often with surprising speed and vigor, and forest regrowth has occurred whenever pressures

on it have been relaxed. This was observed after the Mayan population collapse around 800 CE, after the Great Plague in Europe after 1348, after the initial European encounter with the Americas in 1492, and with agricultural land abandonment in the post-1910 eastern United States and in post-1980 Europe.

Premodern Age (to 1500 CE)

Because crop domestication and the increase and spread of people occurred in largely forested environments, ancient societies everywhere had a cumulatively severe impact on forests. In Europe, Mesolithic cultures (c. 9000–5000 BCE) set fire to the woodland edges to facilitate hunting. The succeeding Neolithic agriculturalists (c. 4500–2000 BCE) had a far greater impact as they felled forests on the fertile loessial soils with stone-and-flint axes to engage in intensive garden cultivation and extensive wheat growing. In order to vary diet, they also ran large herds of pigs, sheep, and especially cattle in woodland and cleared pastures for their meat, milk, blood, and possibly cheese. It was a stable, sedentary society that made full use of the many products of the forest, one calculation being that on average it required 20 hectares of forest land to sustain one person in fuel, grazing, constructional timber, and food.

In Asia, complex and highly organized societies flourished in the forests of the southern and south-eastern parts of the continent. Rotational cutting and cultivation followed by abandonment (swiddening) in forests was accompanied by an intensive garden culture for fruit, spices, and vegetables, and the peculiar and highly innovative development of wet rice cultivation (rice paddies), a technique that stopped

In parts of Asia, fertilizers sparked regrowth of local hybrid poplars (*Populus simonigra*) planted in irrigated sandy soil.

erosion and leaching of the soil in the cleared forest in heavy-rainfall areas. Stock, particularly cattle and pigs, were integral to all parts of the economy.

The evidence for similar processes is unfolding for the Americas. Earliest were the swiddens in the equatorial upland rain-forest areas from as early as 12,000 BCE. From the tropical Gulf of Mexico lowland civilizations of the Olmec and Maya to the less organized tribal groups of the Amazon basin, rain forest was being chopped, burnt, and changed or eliminated. Large patches of the Amazon forest were altered irrevocably by the selection and propagation of useful trees and by different cycles of cultivation, so that the mighty rain forest may be one large cultural artifact. In North America, the earliest food-growing settlements (c. 10,000 BCE) were in the rich bottomlands of the continent's rivers in the South and the Southeast. Similar to the practice of the European Neolithics, flood plains and lower river terraces were cleared, and lower slopes altered as intensive cropping expanded, but unlike the Neolithics, hunting loomed much larger in the economy. The vast eastern temperate woodlands were settled later (after c. 800 CE) but the same imprints are evident, resulting in a mosaic of intensively cultivated cleared lands, abandoned fields with early forest succession, and thinned and altered forests. The great difference between the Americas and Eurasia was the absence of grazing animals in the Americas, which had an effect on the Eurasian forests by preventing regrowth and making clearing/firing worthwhile to promote pasture.

Knowledge about deforestation in Africa is sparse, and with the exception of settlement in savanna-woodland and adjacent belts in west Africa, it may not have been very extensive.

The conclusion is that the impact of early humans on the forest was far greater than expected; it may have been one of the major deforestation episodes in history, which left anything but the pristine forest that is such a feature of the romantic imagination of the past and the environmental rhetoric of the present.

The classical world of the Mediterranean basin provides, for the first time, rich literary detail of wood consumption for shipbuilding, urban heating and construction, and metal smelting, but it is tantalizingly silent about clearing for agriculture (always the greatest cause of deforestation) that must have gone on everywhere. This was to be a common story in later ages too. The chopping down of trees as a prelude to farming and providing food was so commonplace that it simply did not warrant a mention, but settlement patterns and crop figures show how extensive it must have been.

The Middle Ages in western and central Europe were entirely different. Here an energetic, inventive, and rapidly expanding population left ample records of forest clearing through charters, rent rolls, court cases, field patterns, and place names. Clearing was motivated by a strong religious belief that humans were helping to complete the creation of a divine, designed Earth and a desire by lay and ecclesiastical lords to expand rental revenues by encouraging settlement on the forest frontier. Also, individuals wanted to achieve social freedom, property, and emancipation by breaking free of the rigid feudal ties.

Undoubtedly three technical innovations helped raise agricultural production. First, the dominant system of two fields with one fallow was replaced by a three-field system, thus a shortening of the fallow period. This was possible because new crops like oats and legumes helped to fertilize the soil and supplemented animal and human nutrition. Second, the development of the wheeled plow with coulter and moldboard allowed cultivation to move from the

A forest worker fells tree at Ellakanda plantation block, a trial cable-logging site at Bandarawela, Sri Lanka.

light soils onto the heavy moist soils that were usually forested. Third, plowing efficiency was improved by the invention of the rigid horse collar and nailed horseshoes, increasing speed and pulling power, thus favoring the horse over the ox. A major underlying driving force was a sixfold increase of population between 650 and 1350 and the need for more food to avert famine.

Cultivation rose from about 5 percent of land use in the sixth century CE to 30–40 percent by the late Middle Ages. The forests of France were reduced from 30 million hectares to 13 million hectares between around 800 and 1300 CE. In Germany and central Europe, perhaps 70 percent of the land was forest covered in 900 CE, but only about 25 percent remained by 1900.

The various elements interlocked to produce what Lynn White, historian of medieval technology, called “the agricultural revolution of the Middle Ages” (1962, 6), which asserted the dominance of humans over nature. It also shifted the focus of Europe from south to north, from the restricted lowlands around the Mediterranean to the great forested plains drained by the Loire, Seine, Rhine, Elbe, Danube, and Thames. Here the distinctive features of the medieval world developed—a buildup of technological competence, self-confidence, and accelerated change—which after 1500 enabled Europe to invade and colonize the rest of the world. In that long process of global expansion the forest and the wealth released from it played a central part.

Massive deforestation must also have happened in China, but the detail is murky. The population rose from about 65–80 million in 1400 CE to 270 million in 1770, and land in agriculture quadrupled. Large swaths of the forested lands in the central and southern provinces were certainly engulfed by an enormous migration of peoples from the north.

Modern World (1500–c. 1900)

During the roughly four hundred years from 1492 to about 1900, Europe burst out of its continental confines with far-reaching consequences for the global forests. Its capitalistic economy commoditized nearly all it found, creating wealth out of nature, whether it be land, trees, animals, plants, or people. Enormous strains were put on the global forest resource by a steadily increasing population (c. 400 million in 1500 to 1.65 billion in 1900) and also by rising demands for raw materials and food with urbanization and industrialization, first in Europe and, after the mid-nineteenth century, in the United States. In the mainly temperate neo-European areas, settler societies were planted and created. Permanent settlement began in earnest by the 1650s after the near elimination of the indigenes by virulent Old World pathogens, like smallpox, measles, and influenza. The imported Old World crops and stock flourished wonderfully. The dominant ethos of freehold tenure, dispersed settlement, “improvement,” and personal and political freedom led to a rapid and successful expansion of settlement, although much environmentally destructive exploitation also occurred. Tree growth was considered a good indicator of soil fertility in all pioneer societies, and the bigger the trees the quicker they were felled to make way for farms. The United States was the classic example. The pioneer farmer, through “sweat, skill and strength,” (Ellis 1946, 73) was seen as the heroic subduer of a sullen and untamed wilderness. Clearing was widespread, universal, and an integral part of rural life; about 460,300 square kilometers of dense forest were felled by about 1850 and a further 770,900 square kilometers by

1910. “Such are the means,” marveled the French traveler, the Marquis de Chastellux in 1789,

by which North-America, which one hundred years ago was nothing but a vast forest, is peopled with three million of inhabitants. . . . Four years ago, one might have travelled ten miles in the woods . . . without seeing a single habitation. (Chastellux 1789, 29)

It was one of the biggest deforestation episodes ever. A similar process of the pioneer hacking out a life for himself and family in the forest occurred in Canada, New Zealand, South Africa, and Australia. In Australia, for example, nearly 400,000 square kilometers of the southeastern forests and sparse woodland were cleared by the early twentieth century.

In the subtropical and tropical forests, European systems of exploitation led to the harvesting of indigenous tree crops (e.g., rubber, hardwoods), and in time to the systematic replacement of the original forest by “plantation” crops grown by slave or indentured labor. Classic examples of this were the highly

profitable crops of sugar in the West Indies, coffee and sugar in the subtropical coastal forests of Brazil, cotton and tobacco in the southern United States, tea in Sri Lanka and India, and later rubber in Malaysia and Indonesia. In eastern Brazil, over half of the original 780,000 square kilometers of the huge subtropical forest that ran down the eastern portions of the country had disappeared by 1950 through agricultural exploitation and mining. In the state of São Paulo alone, the original 204,500 square kilometers of forest were reduced to 45,500 square kilometers by 1952.

Peasant proprietors were not immune to the pressures of the global commercial market. Outstanding was the expansion of peasant cultivation in lower Burma (encouraged by British administrators) between 1850 and 1950, which resulted in the destruction of about 35,000 square kilometers of imposing equatorial (*kanazo*) rain forests and their replacement by rice. Throughout the Indian subcontinent the early network of railways meant an expansion of all types of crops by small-scale farmers, often for cash, that led to forest clearing everywhere.

The Appleton Paper Mills in Wisconsin, circa 1898. Deforestation accelerated in the twentieth century as the demand for paper and wood products boomed, and the need to clear land for factories and cities shrank forests further. Library of Congress.

Uncolonized Asian societies exploited their forests just as vigorously, commercially, and uncaringly as did their European counterparts. There is evidence from, for example, southwestern India and Hunan Province in south-central China from the sixteenth century onward to show that the commercialization of the forest was well established. In the former, permanent indigenous agricultural settlements existed side by side with shifting cultivation, and village councils regulated forest exploitation by agriculturalists. The forest was not regarded as a community resource; larger landowners dominated forest use locally. Scarce commodities such as sandalwood, ebony, cinnamon, and pepper were under state and/or royal control. In Hunan, a highly centralized administration encouraged land clearance in order to enhance local state revenues so as to increase the tax base and support a bigger bureaucracy and militia. State encouragement was also given to migrations into the forested hill country of south China later on. Simply, forests everywhere were being exploited and were diminishing in size as a response to increasing population numbers and increasing complexity of society. In the subtropical world, change was just slower than that unleashed by the Europeans with their new aims, technologies, and intercontinental trade links, but no less severe. Measures of destruction are hard to come by, but between 1860 and 1950 in South and Southeast Asia, 216,000 square kilometers of forest and 62,000 square kilometers of interrupted or open forest were destroyed for cropland.

During these centuries deforestation was also well underway in Europe itself, which was being colonized internally. This was particularly true in the mixed-forest zone of central European Russia, where over 67,000 square kilometers were cleared between around 1700 and 1914.

The insatiable demand in all societies for new land to grow crops and settle agriculturalists has been matched by a rising demand for the products of the forest themselves. For example, the European quest for strategic naval stores (masts, pitch, tar, turpentine) and ships' timbers made major inroads into the forests of the Baltic littoral from the fifteenth century

onward and those of the southern United States after about 1700. Alternative construction timbers like teak and mahogany were utilized from the tropical hardwood forests since the beginning of the eighteenth century.

The Last Hundred Years

The pace of transformation increased during the first half of the twentieth century. In the Western world demands for timber accelerated. New uses (pulp, paper, packaging, plywood, chipboard) and relatively little substitution of other materials boosted use, while traditional uses in energy production, construction, and industry continued to loom large. The indispensable and crucial nature of timber in many Western economies gave it a strategic value akin to that of petroleum in economies today. In the tropical world the massive expansion of population by more than half a billion on a base of 1.1 billion resulted in extensive clearing for subsistence, accompanied by an expansion of commercial plantation agriculture. In all perhaps 2.35 million square kilometers of tropical forest were lost between 1920 and 1949. The only encouraging feature in the global picture during these years was the reversion of farmland to forest. This had begun in the eastern United States with the abandonment of "difficult" and hard-to-farm lands in New England in favor of easier-to-farm open grasslands, and continued with the abandonment of some cotton and tobacco growing lands in the southern States. A similar story unfolded in northern Europe with "marginal" farms.

The most publicized deforestation—the deforestation everyone thinks of when the word is mentioned—occurred after 1950. Since then the temperate coniferous softwood forests have about kept up with the demands of industrial societies for supplies of timber and pulp. But the focus of deforestation has shifted firmly to the tropical world. Here, better health and nutrition have resulted in a population explosion and an additional 3.5–4.0 billion people. These are often landless people who have moved deeper into the remaining forests and farther up steep forested slopes. They have no stake in the land and therefore

The unrecorded past is none other than our old friend, the tree in the primeval forest which fell without being heard. • **Barbara Tuchman (1912–1989)**

little commitment to sustainable management. In addition chain saws and trucks have moved felling from the province of the large firm to the enterprising individual. Since 1950 about 7.5 million square kilometers of tropical forests have disappeared, Central and Latin America being classic examples. In addition, the tropical hardwood forests are being logged out for constructional timber at a great rate, while wood is cut for domestic fuel in prodigious quantities in Africa, India, and Latin America. Globally, fuel wood—cutting now roughly equals saw timber extraction—about 1.8 billion cubic meters annually compared to 1.9 billion cubic meters. Cutting wood for fuel is forecast to rise rapidly in line with world population increases.

The Future

The long and complex chronicle of deforestation is a significant portion of world history. It is one of the main causes of terrestrial transformation, whereby humankind has modified the world's surface, a process that is now reaching critical proportions. One thing is certain: with an ever-increasing world population (another 2–3 billion by 2020), many will want to exploit resources and the process of deforestation will not end. Others will want to restrict forest use and preserve it. The tensions between exploitation and preservation will be intense.

Delhi Sultanate

In 1192, the Turkic ruler Muhammad of Ghor established the Delhi sultanate, a state that brought Islam and Muslim culture to the northern Indian subcontinent. The combined Hindu and Muslim influences inspired a new culture that laid the groundwork for the achievements of the Mughal Empire, which replaced the Delhi sultanate in 1526.

The Delhi sultanate (1192–1526) was established with the victory of Muhammed of Ghor (d. 1206), a Turkic ruler, over the Rajput king Prithviraj Chauhan, the ruler of Ajmer and Delhi; it represented the emergence of a ruling power that was not indigenous to the region. A new religion (Islam) and culture began to pervade the northern portion of the Indian subcontinent as the Delhi sultanate came to control major areas of present-day India, Bangladesh, and Pakistan. Gradually, Indian culture, which was pluralistic in nature, was enriched by this new cultural infusion. It would be wrong, however, to think of the period of rule by the Delhi sultans as a period of Muslim rule, as categorizing historical periods according to the ruler's religion is against historical norms; and in any case the whole of the Indian subcontinent was never controlled by the sultans.

History

The lure of wealth, religious zeal, and a desire for territorial aggrandizement were factors behind the Turkic conquest from Central Asia. The Turks' advanced military technology, lack of unity among the regional powers, prevailing social tensions, and the apathetic attitude of the common folk facilitated

the Turkic conquest. Muhammad of Ghor was succeeded by his slave and general, Qutb-ud-Din Aybak (d. 1210), and because a number of former slaves ruled during the period 1206 to 1290, this period is sometimes called the slave dynasty, though in reality no sultan was a slave at the time he became ruler, and there were actually three dynasties during this period (1206–1290).

Under the third sultan, Iltutmish (reigned 1211–1236), a permanent capital was established at Delhi; he also expanded the territory controlled by the sultanate. Iltutmish bequeathed a strong form of military despotism to his successors. Raziya Sultana, his worthy daughter and the first Muslim woman ruler of India, became embroiled in the conspiracy of the Group of Forty, a group of Turkic nobles who wished to control the throne. The latter held sway until the coming of Ghiyas-ud-Din Balban (reigned 1266–1287), who destroyed the Forty ruthlessly, strengthened the army, and suppressed any form of dissent.

The establishment of the Khalji dynasty marked the beginning of the ascendancy of Indian (as opposed to Turkic) Muslims. The most important ruler of the dynasty, 'Ala'-ud-Din Khalji (reigned 1296–1316) extended the boundary of Delhi sultanate into southern India. His market reforms, taxation policy, and military administration earned him recognition as one of the efficient rulers of the period. By contrast, the ill-fated experiments of one ruler of the Tughluq dynasty, Muhammad ibn Tughluq (reigned 1325–1351), included an attempt to shift the capital from Delhi to Daulatabad and the introduction of token currency—copper coins, which the sultan made legal tender. Although without intrinsic value, their

value was kept par with gold and silver coins. These experiments brought misery to his subjects.

The Mongol chief Timur (1336–1405) invaded Delhi in 1398, leaving a trail of devastation and weakening the sultanate. The Delhi sultanate was finally overthrown by Babur (1483–1530), founder of India's Mughal Empire (1526–1857), at the first battle of Panipat in 1526.

Administration and Culture

In the beginning, the Delhi sultanate was divided into units called *iqtas*. The owner (*iqatadar*) of each *iqta* collected revenue and supplied army contingents to the sultan. The *iqatadars* became hereditary owners, and abuses crept into the system. Later, a different administrative setup came into being, with the sultan at its leader. The sultan was head of the state and enjoyed absolute power. The sultan's vizier was the prime minister, and there were several different ministries. Religious scholars enjoyed special privileges, and Hindus, as non-Muslims, had to pay a special tax. Despite that burden, the Hindu upper classes led a comfortable life. Although there were conflicts between the Hindu and Muslim ruling elites, common people of both religions lived in harmony, and the aristocracy enjoyed a life of luxury. There was growth of urban centers, and the volume of trade with western Asia, Southeast Asia, and China increased. The sultanate was very much a part of international trade, and Muslim traders from the region helped spread a liberal brand of Islam to Southeast Asia.

The Delhi sultanate oversaw the flourishing of a new cultural era. A new style of architecture emerged that incorporated both Hindu and Muslim motifs. Notable contribution of the Delhi sultans to architecture include the Quwat-ul-Islam mosque, the Qutab Minar, the Siri fort, Alai Darwaza, the cities of Tughluqabad and Firuzabad, and the tomb of Firuz Shah Tughluq (reigned 1351–1388). Nor did the art of painting die out; it was at home in the murals, painted textiles, and manuscripts of the period. Music was patronized by some sultans and provincial rulers;

the most important figure in Indian music during this period, also considered one of India's greatest Persian-language poets, was Amir Khusrau (1253–1325). Credit goes to him for introducing several forms of singing and new ragas. Linguistically, amalgamation of dialects of Hindi and Persian resulted in the beginning of the Urdu language. The contemporary historical writings of Minhaj-us-Siraj, Amir Khusrau, Ziauddin Barani, Shams Siraj Afif, and Yahya bin Ahmad Sirhindi are important source materials for studying different aspects of the Delhi sultanate.

The Sufi (Islamic) and bhakti (Hindu devotional) saints of the period dedicated themselves to the cause of humanity and emphasized the cooperation between the two religious communities. Both preached equality and were against rituals and a caste-based social system. Bhakti saints such as Kabir (1440–1518) and Caitanya (1485–1533) stressed the union of the individual with God through acts of devotion. This period also saw the establishment of a new religion, Sikhism, formalized by Guru Nanak (1469–1539). The Sufi religious mystics offered a common meeting ground for Muslims and non-Muslims. Striving for Hindu-Muslim unity, they created a liberal atmosphere. Their tombs still attract people of both religions.

In sum, the period of the Delhi sultanate was important for Indian history, culture, and society. The new composite culture that began to emerge laid the groundwork for the cultural achievements of the Mughal period.

Democracy

Democratic government requires popular control over public decisions and decision makers, and an equality of respect and the right to be heard between citizens in the exercise of that control. A constitutional democracy imposes codified legal limits on the powers of the government. A separation of powers, or an arrangement of checks and balances, exists between the executive, legislative, and judicial branches of government.

As an organizing principle, constitutional democracy designates a large political community and defines it as inclusive, open, and free. Nations governed by such a democracy are bound by widely accepted guidelines through what is usually a written public consensus. The shared core values include civil liberties, pluralism, tolerance, and wide access to expression in all forms of the media. Sometimes entrepreneurial markets and social rights are also embraced. Constitutional democracy is the most sensible countermeasure to authoritarian and dictatorial regimes, which owe their legitimacy to dynastic tradition, affirmation by religious establishments, or sheer coercion.

How best to conduct the public affairs of human societies has been a challenge throughout history, occupying the minds of important thinkers, such as Plato and Aristotle, from ancient Greece on. Whether such affairs are conducted through providential inspiration, dictatorial rule, or a social contract, no system has been perfect. Any system that has emerged has needed reform to cultivate the goodwill of those governed in a dynamic world in which challenges and needs always change. The most effective way of

quantifying public opinion is through popular elections held periodically in a free and fair manner. These elections sanction delegates through a widespread mandate to discuss and resolve important contemporary political, social, and economic issues of power and authority.

Democracy is rule by the people who reside in a particular political unit (such as the city-state, the Greek polis, especially during the eighth through fourth centuries BCE). However, if democracy is taken to its logical conclusion, a majority of those people assembled in a meeting can reverse long-held traditions or, in extreme cases, arrest and even kill those people who oppose the will of the preponderance of participants—the feared tyranny of the majority. Therefore, the shared interest of free people, especially in entrepreneurial and peaceful settlements, dictates the establishment in a document of a set of fundamental principles that legitimizes and secures the continuity of liberty and civil, political, social, economic, and cultural rights, and serves as the foundation of a viable state. Such a document articulates the standards and goals of a defined community with a publicly expressed affinity to certain human values and philosophical norms.

The viability of constitutional democracy is dependent on a deliberative body, for example, a congress or a parliament. In such a body the citizens of a country have representatives—in at least one legislative branch for each level of government within federal or unitary states—who are elected in free, fair, and periodic elections, and vested with the essence of sovereignty. This deliberative body engages in debates that routinely decide the level of taxation, allocation of budgets, domestic measures, security concerns, foreign relations,

Perhaps America will one day go fascist democratically, by popular vote. • William L. Shirer (1904–1993)

and all other matters of public policy. Constitutional democracy also endorses lobbying and petitioning of those people who hold elected positions.

Constitutional democracy is an antidote to both the oppressive, nondemocratic nature of rule by decree apparent in authoritarianism and the unlimited control inherent in unchecked forms of democracy such as majoritarianism (the practice according to which decisions of a group should be made by a numerical majority of its members). Constitutional democracy is a tolerant and pluralistic framework that prevents laws from depriving minorities or individual citizens or circumventing moral norms through positive law—statutes and ordinances that govern a state. Fundamental rights—such as freedoms of opinion, association, expression, religion and worship, due process in trial, and the ability to pursue personal choices—are guaranteed. This guarantee is made without discrimination on the basis of gender, class, nationality, creed, political opinion, sexual orientation, or other personal characteristics that are irrelevant to individual merit.

Advantages

British Prime Minister Winston Churchill (1874–1965) famously said that democracy, for all its faults, is still better than other political systems: “Democracy is the worst form of government except all those other forms that have been tried from time to time.” Constitutional democracy is a manageable alternative to the chaos necessitated by bringing every decision to the scrutiny of numerous people, except for in the smallest jurisdictions that might feasibly practice some form of direct democracy. It is also an antidote to the potential tyranny of decrees issued by kings, queens, generals, or presidents without the advice and consent of those in whose name they presume to govern. The balancing act of parliaments and the judiciary check the absolute powers that executive privilege might otherwise confer upon rulers.

In a constitutional democracy a legitimate regime can rightfully claim a monopoly on the publicly accepted use of coercion, including violence. Societies

in which parliamentarianism prevails are governed by a relatively open political culture with elections contested by multiple parties and individuals. (In parliamentarianism, also known as the Westminster system, the executive branch’s political party, or a coalition of like-minded parties, must have a working majority in the legislature to remain in power.) Compromise is preferred over confrontation. Rules of conduct and debate and respect for fundamental human rights facilitate basic civil rights such as freedoms of expression, speech, assembly, ideology, affiliation, and religion.

John Locke

John Locke (1632–1704), an influential English political theorist of the Enlightenment (a seventeenth- and eighteenth-century philosophical movement marked by a rejection of traditional social, religious, and political ideas and an emphasis on reason, rationalism, and the scientific method), argued that the proper function of societies and states must be based on compromise and freedoms, that is, civil equality. Deeming human civilizations as having emerged voluntarily from an idyllic state of nature, he would not lend credence to coercion or dynastic authority. Government originates in the consent of the people (the idea of the implied social contract) it presumes to lead and for their benefit alone; its legitimacy is dependent on continuous adherence to such principles.

Locke thus advocated sovereignty based on reciprocal equality—a balance of powers and jurisdiction between the judicial, legislative, and executive branches, prohibiting the subordination of any branch. The French political thinker Montesquieu (1689–1755) later articulated this more explicitly in his separation of powers theory. Locke opposed violence that merely enhances the authority of oppressive rulers rather than protect public order. These ideas, being the modern foundations of constitutional democracy, affected subsequent practices in the Western world, including British, French, and U.S. practices. Locke’s writings were particularly influential in the

Independence Hall in Philadelphia, a symbol of U.S. democracy, as it looked in the nineteenth century.

drafting of the U.S. Declaration of Independence and the U.S. Constitution, while Locke was personally involved in drafting the Fundamental Constitution of the Carolinas.

History

It is widely thought that the idea and practice of democracy has its roots in ancient Greece around two-and-half millennia ago (c. sixth century BCE). Oldest and best known of the Greek democracies is ancient Athens. Recent discoveries, however, suggest that some rudimentary form of democracy might have emerged centuries earlier in the Late Bronze Age (c. 1600–1100 BCE) around Mycenae in the northeastern Peloponnese. Archaeological evidence from ancient Mesopotamia suggests that self-governing assemblies might have originated there and spread east toward the Indian subcontinent and westward to Phoenician

port cities such as Byblos and Sidon, before arriving in ancient Athens.

Wherever the roots of democracy might lie, since people first assembled to decide matters of public policy, they have faced the dilemma of how best to maximize participation while introducing a convenient forum for managing affairs efficiently. Direct democracy sounds ideal. Reality, however, may be quite different. A deliberative, representative polity (political organization) may gain viability by establishing an institutional body for regular legislation by a limited amount of members, elected periodically and fairly.

Athens

In Greece the Athenian lawmaker Solon (c. 630–560 BCE) presented an early version of a participatory constitutional democracy, blended with elements of social justice, in a commercial and cultural center. Earning his distinction as a poet, he purported to correct the excesses of exclusive and oppressive aristocratic control of government. Wealthy landowners used their leverage to exploit a severe economic crisis to deprive poorer town dwellers and peasants of their property and freedom or to force them into exile. Solon was chosen as a chief magistrate with broad authority in 594 BCE by the ruling class that he subsequently challenged. His reforms aimed to improve a flawed system, with roots in the Draconian code (a severe code of laws held to have been framed by the Athenian lawmaker Draco) of 620 BCE, by limiting the absolute power of the upper class.

Solon curtailed the influence of the rich and introduced a more humane and balanced legal code to help debtors. Enhancing the Assembly of the People by creating the Boule (a multiethnic council of middle-income citizens), he limited the authority of the aristocratic Council of the Best Men (Areopagus) and enabled all adult male Athenians to vote and be elected. This partial empowerment was a compromise between various classes and contesting interests and was in contrast to the conservative ways of Athens's main rival, Sparta. Nevertheless, because he did not please a certain constituency, Solon became

so controversial that he left Athens, and tyranny prevailed for decades.

Cleisthenes (c. 570–507 BCE) continued Solon's constitutional reorganization. He made the Assembly of the People the sole legislative body, subordinating magistrates to its jurisdiction, increased the influence of the Boule, deprived the Areopagus of effective power, and ensured wide and deep participation in public life. Cleisthenes made Athenian government more accountable to an inclusive, active political community and thus a role model for subsequent civilizations.

By modern standards Athenian democracy is not quite so democratic in terms of inclusiveness, participation, and the extension of suffrage. While there was not the explicit link between property holdings and democratic rights that would later emerge, there were considerable barriers to participation in Athenian democracy, which was exclusively the preserve of adult male Athenian citizens with military training. And in order to be eligible for Athenian citizenship, one generally had to be directly descended from Athenian citizens on both sides of the family tree. Also explicitly excluded from the practice of Athenian democracy were women, children, slaves and freed slaves, foreigners, and those citizens whose rights had been suspended for some sort of indiscretion.

Britain

Centuries later Britain's Westminster tradition involved unwritten conventions, coupled with the constitutional monarchy variant of parliamentarianism. Beginning with the Magna Carta of 1215–1225 and culminating with the Glorious Revolution during the seventeenth century, a growing degree of universal suffrage for the middle class, independent judiciary, civil rights, and more open political practices replaced the rule of the monarchy and the aristocracy.

From a system prevailing only in Western countries, British (and, to a much lesser extent, Dutch, French, Portuguese, and Spanish) colonialism spread constitutional democracy in communities of European settlers to North America, Oceania (lands of the central and South Pacific Ocean), and southern

Africa, although indigenous residents were usually deprived of its benefits. European colonialism also introduced constitutional democracy to Africa, Asia, and Latin America. But due to the hardships of economic exploitation endured by the colonized, ideas of freedom and human rights reflected by constitutional democracy were tinged by suspicions of hypocrisy, as evidenced by charges against John Locke that he personally benefitted from the slave trade through investments in the Royal African Company.

United States

The formative era of the U.S. version of an effective constitutional democracy is identified primarily with Thomas Jefferson (1743–1826). His agenda of civil nationalism emphasized individual freedoms and the separation of church and state. The core of the 1776 Declaration of Independence was “life, liberty and the pursuit of happiness.” The apex of the formative era was the drafting of a constitution in 1787. The Constitution vested sovereignty in the U.S. people (excluding nonwhites, whose ability to be citizens was in doubt well into the twentieth century) through a hybrid of federal authority and individual states, created the presidency, and granted the federal government the ability to tax citizens and command troops.

The 1791 Bill of Rights assured individual rights and civil liberties such as freedoms of speech, peaceful assembly, and due process. The balance of powers (checks and balances) between the three branches of federal government (executive, legislative, and judicial) was consolidated in 1803 with the *Marbury v. Madison* decision rendered by the Supreme Court. That decision enshrined the doctrine of judicial review in U.S. law, providing an impartial judiciary with the ultimate authority.

Canada

In Canada the Charter of Rights and Freedoms of 1982 shows how a country with more than a century of openness and liberty transforms its legal mechanism to address a political crisis. Canada has had a semblance of a constitutional democracy since the

1867 British North America Act. That act ushered in a degree of sovereignty, which gradually strengthened to amount to a full authority of the Canadian government, within a federal structure, ending British colonial rule. Nevertheless, during the 1970s a secessionist movement in Quebec, a primarily French-speaking province, challenged the legitimacy of Canada, a primarily English-speaking country, for allegedly excluding French-speaking citizens from basic rights on linguistic and ethnic bases.

On the eve of the 1980 referendum that would have allowed Quebec to commence on a path of independence, Canadian prime minister Pierre Elliot Trudeau (1919–2000) felt compelled to promise all Canadian citizens, especially those living in Quebec, that he would initiate comprehensive constitutional reforms that would enshrine a form of pluralistic democracy. Indeed, in 1982 Trudeau's government revised substantially the Canadian constitution, guaranteeing federally, through the Charter of Rights and Freedoms, all basic civil liberties while allowing provinces a strong degree of provincial autonomy. To date, this strategy has helped maintain Canadian unity.

India

Postcolonial India, the most populous country ever to have a constitutional democracy, is an example of how constitutional democracy can shape an emerging nation. After a painful struggle with the British and a war with Islamic communities, India rose to independence in 1947. Jawaharlal Nehru (1889–1964) was India's first prime minister (1947–1964). Although Nehru deployed military force against opponents, he championed an inclusive, pluralistic, polyethnic, multicultural state. Nehru largely endorsed the non-violent practices of the Indian nationalist Mohandas (Mahatma) Gandhi (1869–1948).

By proclaiming a constitutional democracy, Nehru positioned himself, and the Congress Party he led, as the custodian of federal identity, mediating between contesting castes and ethnic, religious, and regional constituencies. The guarantee of freedoms played a major role in securing India's viability in the face of

internal separatist ethnic nationalism and external adversity. In particular Nehru tried to enlist the support of vulnerable groups of people such as women and untouchables through written rights that improved their legal status, although practical changes were slow to come.

Nehru's daughter, Indira Gandhi (1917–1984), served as prime minister from 1966 to 1977. Concerned about India's population growth, she pursued harsh sterilization policies. That pursuit led her to subvert democracy by introducing a state of emergency in 1975. Nevertheless, trying to legitimize her deeds, she felt compelled two years later to call parliamentary elections, which she lost. Gandhi surrendered power freely to her opponents; she returned to office in 1980. She was murdered in 1984 by Sikh extremists who purportedly acted to avenge the desecration of their holy sites in her fight to assert her control over all segments of Indian society.

United States, Post–September 11

As part of the U.S. war on terrorism after the terrorist attacks against New York City and Washington, D.C., on 11 September 2001, the U.S. Congress enacted the controversial Patriot Act in November 2001. The act curtailed civil liberties for a limited time because of national security concerns, causing some people to be concerned about the long-term impact on constitutional guarantees of freedom of speech and expression. The United States also attempted to introduce constitutional democracy to Afghanistan and Iraq after liberating the two nations from oppressive rule in 2001 and 2003, respectively. As of 2010 the outcome of those attempts remains uncertain. Some critics maintain that democracy cannot successfully be externally imposed. If it is to take root it must be implemented and owned by the people, for the people.

Descartes, René

(1596–1650)

FRENCH PHILOSOPHER

Even though the seventeenth-century French philosopher René Descartes has been remembered primarily for his contributions to Western philosophy, he also showed a curiosity about many aspects of the natural world. His mechanistic and rationalistic methods have been criticized as often as they have been praised, but they provided a framework for subsequent scientific inquiry.

René Descartes was the leading French philosopher of the seventeenth-century scientific revolution. Although now best known, and commonly vilified, for his defense of mind/body dualism and for his quest for certainty in the theory of knowledge, Descartes was primarily interested in studying the natural world and the human body. His global influence as the intellectual point of origin of modern Western subjectivity, the evil demon of modern philosophy, is undeniable. But it masks the stranger work of the historical figure, who was as puzzled by meteors and by medicine as by metaphysics and method, and more interested in passion, psychosomatics, and perception than in rationality and the soul.

Born in La Haye (now Descartes) in Touraine, and educated at the Jesuit college of La Flèche, Descartes decided on a life of inquiry in his early twenties after studying mechanics and music, and after a series of powerful dreams. He developed a systematically mechanical account of nature, modeling his cosmology and physics on the behavior of fluids, which also plays a key role in his remarkable physiological theories. Descartes settled in Holland in the late 1620s; by 1632 he was in Amsterdam, “dissecting the heads of various animals” to “explain what imagination,

memory, etc. consist in” (Descartes 1985–1991, Vol. 3, 40). But when he heard of Galileo’s condemnation in 1633, Descartes abandoned plans to publish works on the nature of matter and the body.

Descartes definitively rejected the Christian-Aristotelian idea that biological matter has intrinsic powers or built-in ends, claiming that its capacities arise rather from the complex configurations and combinations of physical particles in motion. He was concerned to defend the orthodox picture of the *soul* as nonphysical and immortal, but he denied that *life* was also due to immaterial powers. His posthumous work *L’homme* (*The Treatise on Man*) describes a fictional world of soulless “earthen machines,” mobile automata like the hydraulic statues in “the gardens of our kings.” Descartes’ physiology relied heavily on “animal spirits,” fast-moving but material fluids that flow through the nerves and the pores of the brain.

Descartes notoriously claimed that the human soul interacts with the body-machine by way of the pineal gland, swaying on its supporting network of arteries and directing the flow of animal spirits through the tubes of the brain tissue. Even in creatures without souls, he posited, ordinary cognitive processing involves the construction and reconstruction of patterned traces on the surface of this gland. Descartes had seen in dissection that nonhuman animals also had a pineal gland. So although he did argue that beasts are machines, he thought that these machines are capable of representation, memory, and even sentience and dreams. Despite the old story that he vivisected a dog on his kitchen table, Descartes offered no justification for cruelty to animals. Far from exclusively privileging the rational soul, his work substantially restricted its role and scope. The bodies of

Each problem that I solved became a rule which served afterwards to solve other problems. • René Descartes (1596–1650)

Frans Hals, *Portrait of René Descartes* (1649). Oil on panel. Statens Museum for Kunst, Copenhagen.

the Cartesian automata are not mere objects cut off from the world, responding passively to the whim of the soul, but are fully and holistically embedded in the buzzing whirl of the fluid-filled cosmos.

Many readers encounter Descartes only through his writings on metaphysics and epistemology. In *Discourse on the Method* (1637) and the *Meditations* (1641), Descartes concocts a sequence of radically skeptical scenarios to challenge our trust in traditional beliefs, and to conclude that he can know with certainty his own existence as a “thinking thing” (*res cogitans*). These works have considerable literary and psychological power: the *Discourse* offers an autobiographical fable about Descartes’ individualistic path to knowledge, while the *Meditations* brilliantly uses the jargon of scholastic Aristotelian philosophy against itself, in making theological space for the ongoing mechanistic investigation of the natural world.

In the seventeenth and eighteenth centuries Cartesianism (Descartes’ philosophical doctrine) was attacked less for its incoherent dualism than for the specter of atheistic materialism that both conservatives and enthusiasts read into it. One story, circulated in the eighteenth century to blacken Descartes’ reputation, concerned his illegitimate daughter Francine: having allegedly conceived the child with a housemaid in order to study reproductive processes at close quarters, the philosopher built and carried around a doll in the form of a life-size replica of the child after Francine’s death from scarlet fever (which the historical Descartes called the greatest sorrow of his life).

In the 1640s, Descartes continued to work on recalcitrant problems about physiology and human nature. He constructed a sophisticated but bizarre embryology, and, under persistent questioning from his correspondent Princess Elizabeth of Bohemia, he further developed his views on psychosomatic interaction. In *The Passions of the Soul* (1649) he linked medicine and morality by attending to the individualized dynamics of the emotional life and the union of mind and body. Descartes, who had long been fascinated by schemes for prolonging longevity, died after a harsh Swedish winter tutoring Queen Christina.

Philosophers of many distinct persuasions have since defined their projects in opposition to a vision of Cartesianism as a philosophy of exact order, reason, and pure subjectivity; but modern scholarship strongly suggests that Descartes himself was not that kind of Cartesian.

Desertification

Experts disagree over the current rate at which arable land is becoming desert, to what extent human activities are responsible, and whether the process is reversible. Yet events such as the Dust Bowl of the 1930s in the United States are compelling evidence of a link between desertification and human misuse of the land.

Desertification is the process of land becoming desert, as from human mismanagement or climate change. It remains a controversial issue with regard to definition, nature, rate of spread, irreversibility, and causation. Nonetheless, it is a serious example of land degradation in dry lands. Deserts have repeatedly expanded and contracted during the last few millions of years in response to climate changes, but their margins are now being affected by a suite of increasing human pressures that depletes soil and vegetation resources.

Desertification was first used as a term, but not formally defined, by a French forester named “Aubreville” in 1949, and for some years the term *desertization* was defined as “the spread of desert-like conditions in arid or semi-arid areas, due to man’s influence or to climatic change” (Rapp 1974, 3).

Different experts have defined *desertification* according to its cause. Some definitions stress the importance of anthropogenic (human-caused) actions. The scientist Harold E. Dregne says, “Desertification is the impoverishment of terrestrial ecosystems under the impact of man. It is the process of deterioration in these ecosystems that can be measured by reduced productivity of desirable plants, undesirable alterations in the biomass [the amount of living matter] and the diversity of the micro and macro fauna and flora,

accelerated soil deterioration, and increased hazards for human occupancy” (Dregne 1986, 6–7).

Other studies acknowledge the possible importance of natural climatic controls but give them a relatively lesser role. In a report for the U.S. Department of the Interior / Bureau of Land Management, *desertification* is defined as “the sustained decline and/or destruction of the biological productivity of arid and semi arid lands caused by man made stresses, sometimes in conjunction with natural extreme events. Such stresses, if continued or unchecked, over the long term may lead to ecological degradation and ultimately to desert-like conditions” (Sabadell et al. 1982, 7).

Other experts are more even-handed with respect to the balance of anthropogenic and natural causes: “A simple and graphic meaning of the word ‘desertification’ is the development of desert like landscapes in areas which were once green. Its practical meaning . . . is a sustained decline in the yield of useful crops from a dry area accompanying certain kinds of environmental change, both natural and induced” (Warren and Maizels 1976, 1).

Experts are not sure how extensive desertification is or how fast it is progressing. The lack of agreement on the former process makes determining the latter difficult, prompting some to remark, “Desertification will remain an ephemeral concept to many people until better estimates of its extent and rate of increase can be made on the basis of actual measurements” (Grainger 1990, 145).

The United Nations Environment Programme (UNEP) has played a pivotal role in the promotion of desertification as an environmental issue, as is made evident by this statement from *The World*

The name written in the sand by this Mauri man is “Arbweir,” the ancient name for Chinguetti. Founded in the tenth century, and considered the seventh holy city of Islam, the old city is now buried by sand. FAO of the United Nations.

Environment 1972–1992: “Desertification is the main environmental problem of arid lands, which occupy more than 40 per cent of the total global land area. At present, desertification threatens about 3.6 billion hectares—70 percent of potentially dry lands, or nearly one-quarter of the total land area of the world. These figures exclude natural hyper-arid deserts. About one sixth of the world’s population is affected” (Tolba and El-Kholy 1992, 134).

Some scholars, however, have been critical of UNEP’s views on the amount of land that is desertified. They state: “The bases for such data are at best inaccurate and at worst centered on nothing better than guesswork. The advancing desert concept may have been useful as a publicity tool but it is not one that represents the real nature of desertification processes” (Thomas and Middleton 1994, 160).

Despite its critics, UNEP continues to support issues of desertification. UNEP helped established the U.N. Convention to Combat Desertification (UNCCD), which holds an international World Day to Combat Desertification and Drought on 17 June. These worldwide annual events supported by UNEP and the UNCCD seek to raise awareness and promotion of desertification issues. In 2006, UNEP focused the international World Environment Day (held annually on 5 June) on desertification issues with the theme “Don’t Desert Drylands.”

Rates of Desertification

Experts have conducted relatively few reliable studies of the rate of desert advance. In 1975, the British

ecologist Hugh Lamprey attempted to measure the shift of vegetation zones in the Sudan in Africa and concluded that a portion of the Sahara Desert in Sudan had advanced by 90 to 100 kilometers between 1958 and 1975, with an average rate of about 5.5 kilometers per year. On the basis of analysis of remotely sensed data and ground observations, however, other scholars found limited evidence that this advance had taken place (Helldén 1984). One problem is that substantial fluctuations in vegetation production may take place from year to year. Meteorological satellite observations of green biomass production levels on the southern margins of the Sahara Desert have revealed such fluctuations.

The International Soil Reference Center in the Netherlands conducted a global assessment by soil degradation on behalf of UNEP during the late 1980s and early 1990s. The center used a Geographical Information System to analyze data collected through a clearly defined, but largely qualitative, methodology. Despite its flaws, the Global Assessment on Human Induced Soil Degradation (GLASOD) provided a database through which experts could assess susceptible dry land soil degradation in terms of spatial distribution, contributory degradation processes, and relationships to land use.

The GLASOD estimated that during the late 1980s and early 1990s approximately 1 billion hectares, equivalent to 20 percent of the susceptible dry lands, had experienced accelerated soil degradation caused by human activities. Water erosion was identified as the major physical process of degradation in 48 percent of this area and wind erosion in 39 percent.

Chemical degradation (including salinization) was dominant in just 10 percent of the area, and physical changes such as compaction and crusting in just 4 percent. The severity of degradation was described by the GLASOD as strong or extreme in 4 percent of the susceptible dry lands. This figure relates to lands that have had their original biotic (relating to living organisms) functions of the soil destroyed and that are irreclaimable without major restorative measures.

The spatial character of desertification is also the subject of controversy. The spread of desertlike conditions is not, as popularly supposed, an advance over a broad front in the way that a wave overwhelms a beach. Rather, it is like a rash that tends to be localized around settlements. Fundamentally, “the extension of desert-like conditions tends to be achieved through a process of accretion from without, rather than through expansionary forces acting from within the deserts” (Mabbutt 1985, 2). This distinction is important because it influences perceptions of appropriate remedial or combative strategies.

Experts have debated whether desertification is irreversible. In many cases where ecological conditions are favorable because of the existence of such factors as deep, sandy soils, vegetation recovers after excess pressures are eliminated. The speed of recovery depends on how advanced deterioration is, the size of the area that is degraded, the nature of the soils and moisture resources, and the nature of local vegetation. Much desert vegetation is adapted to drought and to harsh conditions and often has inbuilt adaptations that enable a rapid response to improved circumstances.

Nonetheless, long-term monitoring elsewhere tends to reveal that in certain circumstances recovery is so slow and so limited that it may be appropriate to talk of “irreversible desertification.” For example, in southern Tunisia tracks made by tanks and wheeled vehicles during World War II are still apparent on the ground and in the devastated and unregenerated vegetation.

Causes of Desertification

The causes of desertification remain controversial. Experts have asked whether it is the result of temporary serious droughts, long-term climatic change,

A man pumps water from an artesian well in North Africa to irrigate the fields. Adequate irrigation in this arid region is necessary for buffalo breeding.

Courtesy of the Food and Agriculture Organization of the United Nations.

or human actions degrading the biological environments in arid zones. No doubt severe droughts do take place, and their effects become worse as human and domestic animal populations increase. The devastating drought in the Sahel (the semidesert southern fringe of the Sahara Desert) from the mid-1960s caused greater ecological stress than the droughts of 1910–1915 and 1944–1948, largely because of increasing anthropogenic pressures.

Experts have discredited the concept that climate is deteriorating through postglacial progressive desiccation. However, numerous studies of meteorological data (which in some cases date back as far as 130–150 years) do not allow experts to reach any firm conclusions on systematic long-term changes in rainfall, and the case for climatic deterioration—whether natural or aggravated by humans—is not proven. Indeed, Rapp wrote that after consideration of the evidence for the role of climatic change in desertification his conclusion was “that the reported desertization northwards and southwards from the Sahara could not be explained by a general trend towards drier climate during this century” (Rapp 1974, 29).

Woodcutting is a serious cause of vegetative decline around the area to the south of the Sahara. Many people depend on wood for domestic uses, and the collection of wood for charcoal and firewood is especially serious in the vicinity of large urban centers. Likewise, the recent drilling of wells has enabled rapid multiplication of domestic livestock numbers and large-scale destruction of the vegetation in a radius of 15–30 kilometers around them. Given this

localization of degradation, amelioration schemes such as local tree planting may be partially effective, but ideas of planting massive belts as a *cordon sanitaire* (protective barrier) along the desert edge (whatever that is) would not halt deterioration of the land beyond this belt. The deserts are not invading from without; the land is deteriorating from within.

Clearly, therefore, a combination of human activities (e.g., deforestation, overgrazing, and plowing) with occasional series of dry years leads to the presently observed desertification. The process also seems to be fiercest not in desert interiors, but rather on the less arid marginal areas around them. The combination of circumstances particularly conducive to desert expansion can be found in semiarid and subhumid areas—where precipitation is frequent and intense enough to cause rapid erosion of unprotected soils and where humans are prone to mistake short-term economic gains under temporarily favorable climatic conditions for long-term stability.

These tendencies toward bad land-use practices partly result from the imposition of state boundaries on many traditional nomadic societies, restricting their migration routes, or from schemes implemented to encourage the nomads to become sedentary. Some of their traditional grazing lands have been taken over by cash-crop farmers. The traditional ability to migrate enabled pastoral nomads and their stock to make flexible use of available resources according to season and yearly variations in rainfall and to move away from regions that had become exhausted after a long period of use. As soon as migrations are stopped and settlements imposed, such options are closed, and severe degradation occurs.

People have suggested not only that deserts are expanding because of human activity, but also that the deserts themselves were created by human activity. People have proposed, for example, that the Thar Desert of northwest India is a postglacial and possibly a postmedieval creation, and others have suggested that the vast Sahara Desert itself is largely human made (Ehrlich and Ehrlich 1970). This proposal is not accurate. The Sahara, although it has fluctuated in extent, is many millions of years old, predates human life, and is the result of its climatic situation.

Possibly the most famous case of desertification associated with soil erosion by deflation was the Dust Bowl of the 1930s in the United States. In part the Dust Bowl was caused by a series of unusually hot, dry years that depleted the vegetation cover and made the soils dry enough to be susceptible to wind erosion, but the effects of this drought were worsened by years of overgrazing, poor farming techniques, and the rapid expansion of wheat cultivation in the Great Plains. The number of cultivated hectares doubled during World War I as tractors (for the first time) were employed in the thousands. In Kansas alone the wheat area increased from less than 2 million hectares in 1910 to almost 5 million in 1919. After the war wheat cultivation continued apace, helped by the development of the combine harvester and government assistance. Over large areas the tough sod, which had exasperated earlier homesteaders, had given way to friable (easily crumbled or pulverized) soils of high erosion potential. Drought, acting on damaged soils, created the “black blizzards.”

Dust storms are still a serious problem in parts of the United States. For example, in the San Joaquin Valley of California a dust storm caused extensive damage and erosion in 1977. More than 22 million metric tons of soil were stripped from grazing land within a twenty-four-hour period. Although the combination of drought and a high wind (as much as 300 kilometers per hour) provided the predisposing natural conditions for the stripping to occur, overgrazing and the general lack of windbreaks in the agricultural land played a more significant role. In addition, broad areas of land had recently been stripped of vegetation, leveled, or plowed up prior to planting. Other quantitatively less important factors included stripping of vegetation for urban expansion, extensive denudation of land in the vicinity of oilfields, and local denudation of land by vehicular recreation. Elsewhere in California dust yield has been considerably increased by mining of dry lake beds and by disturbance of playas (flat-floored bottoms of undrained desert basins that become at times shallow lakes).

A comparable acceleration of dust storm activity occurred in the former Soviet Union. After the “Virgin Lands” program of agricultural expansion during the

1950s, dust storm frequencies in the southern Omsk region increased on average by a factor of 2.5 and locally by factors of 5 to 6.

Desertification is not restricted to heavily populated lands with large agricultural and pastoral populations. As the examples of the U.S. Great Plains and California illustrate, high technology, non-labor-intensive land, and water use can also cause severe degradation.

Human-induced desertification is not new. Although people often focus on the Dust Bowl years of the 1930s and the current degradation of the Sahel, desertification has been the subject of great interest in the Mediterranean area since classical times. Likewise, some evidence indicates that more than four thousand years ago Mesopotamia was suffering from chemical degradation of soils and crop yield reductions as a consequence of the adoption and extension of irrigation. Nevertheless, land degradation is not the inevitable consequence of increasing population densities and land-use intensification, and many techniques are available for desert reclamation.

Deserts

Two types of deserts—tropical and temperate—occupy approximately one third of the planet. While thought to be vast areas of limited resources, the usefulness of arid climates throughout history has depended on the social interaction between the climate and a given society. Analyzing hunter-gatherer and nomadic pastoralist societies has given insight to the influence that desert regions have had on human development.

Deserts cover approximately 30 percent of Earth's surface. A rudimentary classification divides them into two broad types: hot deserts (tropical and subtropical deserts) and temperate or midlatitude deserts. Hot deserts, in which temperatures remain high or very high all year round, are found around the tropics in both hemispheres between latitudes 20° and 30° north and south. In temperate deserts, temperatures differ widely between winter and summer (in winter there is often at least one month in which the mean temperature falls below 5°C, and snow may accumulate for several days). Such deserts are found mainly in the interior of Eurasia and in the Southwest of North America. Besides these two broad classes there are other types that in part coincide with tropical deserts, but whose formation is affected by different factors such as cold coastal currents.

Despite their great diversity, the Earth's arid zones share some common characteristics, principally their excessive dryness, which is the result of high temperatures and low, irregular rainfall. The irregularity of rainfall explains another typical characteristic of dry ecosystems: large fluctuations of biomass above and below very low mean values.

Apart from deep subterranean resources, which in most cases remained unexploited until the twentieth century, deserts provide two important kinds of natural resources: scarce but relatively long-lasting water and food resources, and episodic but abundant resources (such as a sudden deluge of rain after which a pasture may develop). In any event, it must be emphasized that it is the interaction, by way of technology and social relations, between a given society and an arid environment that causes certain aspects of a desert to be perceived as either limitations or as resources.

Hunter-Gatherer Societies

Some hunter-gatherer societies of semiarid zones survived into the nineteenth century in America and into the twentieth century in Australia and southwestern Africa. In general these societies had little ability to modify their environment (although they sometimes did so with fire), and they depended on the spontaneous reproduction of spatially dispersed natural resources. They all displayed an astonishing knowledge of their ecosystems and were able to exploit a large variety of ecological niches, which constituted their productive base. They lived in small groups around temporary sources of water. When the water dried up or the resources situated at a short distance from the pool ran out, they were obliged to move away and find another source of water, which means they were constantly on the move. Lack of water was an almost absolute constraint for them; if food was located too far from the water, they could not exploit it and therefore it did not constitute a resource. Different local groups maintained close kinship relations or alliances

Eugène-Alexis Girardet, *Caravan In The Desert*. Oil on canvas. Mobility and the lack of fixed settlements have always given great military advantages to desert peoples.

with neighboring groups in the same or nearby territories. When there was extreme drought or shortage of food, these social relations allowed them to move into territories occupied by their relatives and allies. It has been suggested that the enormous complexity in the kinship systems of some Australian Aborigines, which created strong ties of obligation among different groups, may have been a way of adapting to the uncertain nature of arid environments.

Nomadic Pastoralists

For thousands of years the typical way of life in the deserts of Eurasia and Africa (though not in those of America or Australia) has been that of nomadic pastoralism, a complex, sophisticated mode of subsistence that has played a major role in the history of the Old World. Most researchers believe that nomadic pastoralism arose at the edges of cultivable zones after the Neolithic advent of agriculture and domestication of animals, in regions that were too dry for the development of settled agriculture and cattle raising.

Nomadism specialized in exploiting an ecological niche that the mixed economies (sedentary agriculture and stockbreeding) could not take advantage of. It seems that almost all nomad societies originated directly or indirectly in the Near East. This region, which suffers acute summer droughts or has clearly arid climates, was inhabited by wild animals (goats, sheep, dromedaries) that, owing to their specific characteristics, fulfilled two conditions: they were easily domesticated and were more or less naturally adapted (or could become so, with the help of man) to the arid or semiarid environmental

conditions. The other early agricultural and cattle-raising centers of the world, in Asia and America, were not populated with these kinds of animals. Some argue that pastoral nomadism arose independently in the Sahara, but that theory continues to be controversial.

A secondary center of nomadic pastoralism may have had its origin in the steppes of southern Russia, where it would have emerged between the third and second millennia BCE in mixed-economy societies of eastern Europe. In the south of Russia, the horse, domesticated around 3000 BCE, gave herders of sheep and goats (which had originated in the Near East) great mobility. The theory is that the domestication of the Bactrian camel (between the third and second millennia BCE), which is similar to the dromedary but better adapted to cold winters, allowed nomads to penetrate the deserts of central Asia. The discovery of Caucasian mummies, some of them from the second millennium BCE, and of texts written in Indo-European languages in the desert of Taklimakan (in the northwestern Chinese region of Xinjiang) may testify to the extent of this movement.

Analyzing the way nomadic societies interact with the environment helps us to understand the great influence that arid and semiarid regions have exercised on the development of Eurasian and African civilizations. Nomadic pastoralism, as a mode of subsistence, is essentially unstable and expansionist. Herds undergo great fluctuations in size and composition in arid environments. Both ethnographic studies and computer techniques demonstrate the potentially explosive growth of a simple flock of sheep or goats.

The tall Saguaro cacti, pictured here outside Tucson, Arizona, bloom in May and June in the temperate deserts of the southwest United States. Photo by Jane M Sawyer (www.morguefile.com).

Nomadic societies exploit this potential in order to accumulate a lot of animals. From the standpoint of basic units of production, it is an intelligent and adaptive response to environmental fluctuations, but on a regional scale it prepares the way for social and ecological disaster. Assertions that nomads, although they do not consciously attempt to modify their environment, create their own steppes and deserts may contain a certain element of truth. The combination of sudden fluctuations and expansive tendencies gives rise to another of the most well-known aspects of nomadic societies: quick and radical shifts along migratory tracks, which sometimes historically appear as invasions or attacks on settled civilizations. It should be remembered that mobility and the lack of fixed settlements has always given great military advantages to desert peoples.

Nomads exploit their resources in small units of production (households or encampments), but, as with hunter-gatherers, these basic units are linked to each other, generally by means of kinship relations.

It is these links that form the basis of larger units when organizing migratory tracks, regulating rights of access to grazing land, and when facing environmental changes. It is membership in these higher-ranking units that in fact grants rights to territory and its resources. As in many hunter-gatherer societies, among nomads kinship relations have great importance because they operate like economic institutions. The manner in which hunter-gatherers and pastoral nomads relate to nature is very different, however. Whilst the hunter-gatherers exploit a great variety of ecological niches in different places and seasons, the nomads always exploit the same basic resource: pasture (either in different environmental zones or in the same one). Whereas the hunter-gatherer's territorial system is based on moving himself towards the resources, that of the nomad involves moving an entire infrastructure of production, with little regard to the regional availability of microresources (such as small mammals and birds, and wild nuts and fruit, all of which are important to hunter-gatherers). For

As a matter of fact, an ordinary desert supports a much greater variety of plants than does either a forest or a prairie. • Ellsworth Huntington (1876–1947)

the hunter-gatherer the great waterless spaces of the desert represent a constraint that prevents him from exploiting resources that are too remote from pools and streams. For the nomad, those spaces only represent a relative limitation, since he can travel long distances transporting water on his animals.

Trading Routes and Oases

From the Atlantic to western China, deserts form a gigantic arid belt that for centuries separated the principal civilizations of the Old World. The nomads, on their constant journeys in search of new pastures, discovered the routes that would allow Chinese silk to travel to Europe across the deserts of central Asia, and that would move gold, ivory, and slaves from tropical Africa to the Mediterranean across the Sahara. They became intermediaries operating between ecologically and culturally different regions, which allowed them to divert surpluses from the agrarian societies of Africa, Europe, and Asia to the arid lands. Thus there emerged, in the oases and at the edges of deserts, fabulously wealthy cities, such as Palmyra, Petra, Samarqand, Timbuktu (Tombouctou), and Almería, in extremely poor environments. The wealth of medieval Islam, which culturally unified the deserts of Asia and Africa, is very much connected with the control of trade between remote civilizations and with the irrigation systems in arid countries.

The oases, like islands in the sea, played a crucial role along the trading routes. But life in these landlocked islands would have been impossible without agriculture, and the main limiting factor for the growth of plants in deserts is water. What characterizes the agriculture of oases is the use of ingenious techniques and complex irrigation systems that permit the extraction and exploitation of water from surface aquifers. The expansion of the Arabs in the Middle Ages helped to spread hydraulic technologies and crops from different regions. The result was the appearance of agricultural ecosystems that were largely freed from the environmental constraints of arid climates, in which man was able to introduce species

from different regions. Before the discovery of America the greatest relocation of vegetable species in history occurred precisely across the deserts and oases of Asia and Africa in the medieval Islamic world.

The term *détente* is often used to describe the improvement in relations between political parties or nations. Though most commonly associated with President Nixon's Cold War policy, *détente* has been used to describe the peaceful agreements between many nations throughout history. It is not commonly used in political language during the twenty-first century, but the term's impact on historical relations remains significant.

In the field of international relations and diplomacy, *détente* means relaxation of tensions between two or more hostile powers. *Détente* may lead to further rapprochement, or improved relations, and may culminate in an entente, or understanding, and possibly even an alliance. In French the word *détente* means relaxation or slackening. During the classical period of European diplomacy, usually seen as the nineteenth and early twentieth centuries, *détente* had a very specific and exact technical meaning. However, during the period from 1963 until the late 1980s the term entered into the mainstream of public debate and was used in the context of relations between the Cold War superpowers, the Soviet Union and the United States.

Détente and Classic Diplomacy

Diplomats of the nineteenth century saw *détente* as the first stage in improvement of relations between states. *Détente* usually implied informal or formal contacts between statesmen and diplomats of rival countries with the objective of gaining preliminary

agreement on ways to resolve outstanding grievances. A prime example can be found in the successful *détente* that took place between Britain and France during the years from 1898 to 1904. Historically France and Britain had been bitter rivals and had fought many wars, most notably the French Revolutionary and Napoleonic wars of 1792 to 1815. Imperial rivalry between the two countries continued throughout the nineteenth century. In 1898 France and Britain came close to war during the Fashoda incident, a confrontation over possession of the African territory of Sudan. The crisis was resolved only when the French decided that war with Britain was not in their national interest. Soon after the crisis the French indicated to the British their desire for improved relations. Progress was very slow, and the next step was taken only in May of 1903, when King Edward VII of Britain visited Paris. Soon after, Émile Loubet, the president of France, paid a return visit to London. Behind the scenes diplomats had been negotiating to resolve outstanding disputes between the two countries. The efforts of the diplomats culminated on 8 April 1904 when France and Britain signed the Entente Cordiale, which marked a new beginning in relations between the two historic rivals. Between 1904 and 1914 Britain and France drew steadily closer together, primarily because of the perceived threat from Germany. The British were reluctant to enter into a formal alliance with the French, but military staffs from the two countries held secret talks and discussed war plans. By 1914 Britain and France were effectively allies. But the first step had been taken during the long process of *détente* from 1898 to 1904.

Détente and the Cold War

During the Cold War the term *détente* was used to describe a policy pursued by President Richard Nixon (1913–1994), first elected in 1968, and his chief foreign policy adviser Henry Kissinger (b. 1923) toward the Soviet Union. The *détente* advocated by Nixon and Kissinger had earlier echoes. The 1963 Cuban missile crisis convinced many in both the USSR and the United States that tensions between the two superpowers had to be reduced. In the late 1950s Soviet premier Nikita Khrushchev had promoted a form of *détente* that he referred to as “peaceful coexistence.” Today, however, *détente* is most often associated with Nixon and Kissinger.

Nixon and Kissinger wanted to reduce Cold War tensions by engaging the USSR in a series of agreements on a wide range of issues. They hoped that the Soviets would find a greater incentive in maintaining good relations with the United States and the West than confronting and challenging American interests around the world. The Nixon-Kissinger initiatives

resulted in the signing of a host of agreements during Nixon's time in office. The most important agreements were signed during a summit meeting between Nixon and Soviet president Leonid Brezhnev in Moscow in May 1972. The two leaders signed the Interim Agreement on the Limitation of Strategic Offensive Arms, known popularly as SALT I (SALT is an acronym for Strategic Arms Limitation Talks), which limited the number of intercontinental ballistic missiles that each side could possess. An additional agreement placed restrictions on antiballistic missiles. Nixon and Brezhnev also agreed to begin talks aimed at scaling back nuclear weapons in Europe and endorsed a document outlining general principles of their new relationship. Later in 1972 a major trade deal led to the sale of American wheat to the USSR. Nixon resigned office in 1974 in the wake of the Watergate scandal, but Kissinger continued as secretary of state under the new president, Gerald Ford. In July 1975 the Helsinki Final Act, the keystone of *détente*, was signed by thirty-five countries. Under the terms of the Final Act, the Soviets promised to respect human rights in

If this phrase of the “balance of power” is to be always an argument for war, the pretext for war will never be wanting, and peace can never be secure. • **John Bright (1811–1889)**

exchange for Western recognition of post-1945 territorial boundaries in Eastern Europe.

However détente was already under attack from hard-liners in the United States who refused to trust the Soviets. They believed that the Soviets were only using détente to lull the West into a false sense of security while continuing to seek advantages wherever and whenever they could. Critics of détente in the United States pointed to perceived Soviet gains in Africa and continued Soviet human-rights violations. The Soviets charged that the United States was trying to shut them out of the Middle Eastern peace process. The presidency of Jimmy Carter, who held office from 1976 to 1980, saw the deterioration of détente, despite the conclusion of SALT II in 1979. The Soviet invasion of Afghanistan in 1979, followed the next year by the election of Ronald Reagan as president of the United States, marked the end of détente. Détente was revived as a policy late in the 1980s as Mikhail Gorbachev of the USSR, along with his counterparts in the White House, Ronald Reagan and George H. Bush, sought to end the Cold War. By that point the term *détente* was seldom used publicly by any of these leaders, since it was so strongly associated with Nixon, Kissinger, and the 1970s.

Détente has gone from being a technical term used by diplomats to a term associated with a contentious phase of the Cold War. Although seldom heard in public debate any longer because of its controversial

past, détente in fact forms a crucial component of international diplomacy.

Diasporas

When peoples of a culture are forced to leave their homeland for political, economic, social, or other reasons, some do not fit neatly into their new host countries. Many of these groups are classified as diasporas: communities not fully integrated into a settlement. Diasporas play an increasingly important role in politics, conflict, and trade as millions of people are detached from, yet emotionally linked to, distant homelands.

The labeling of a minority population as a diaspora points to its origins, its displacement, and its ongoing connections to a far-off homeland. It suggests that members of the group remain distinct from the people among whom they live. Popular and scholarly use of the term *diaspora* has changed substantially over the centuries. A recent scholarly debate over just how widely the term can be applied has not yet reached a satisfactory conclusion.

Early Use of the Term

Over two millennia ago, the Greek historian Thucydides used *diaspora* to describe those driven from their homes during the Peloponnesian War (431–404 BCE). But for other Greek speakers, the term had a much broader meaning; it referred to the dispersion of Greeks around the Mediterranean and into western Asia between 800 and 600 BCE. These were not refugees but merchants and colonizers who formed distinctive Greek settlements amidst peoples of other cultures. The word *diaspora* suggested that like seeds, migrants could travel great distances, yet once they took root, they would grow into familiar forms: Greeks

scattered outside Greece nonetheless remained culturally Greek and proud of their origins.

Perhaps because the term *diaspora* appeared in Greek translations of the Bible describing the exile of Jews, the meaning of the term has subsequently narrowed. Hebrew speakers initially preferred the term *galut* (exile) to describe Jews forced into exile after the destruction of the Temple of Jerusalem in 586 BCE. But over the centuries, the term *diaspora* was applied so often, so consistently, and in so many European languages to Jews who had scattered while escaping from persecution that the earlier, broader Greek meaning of the term seemed almost completely forgotten.

Theorists have used other terms for minority groups formed by forced migrations, calling them involuntary migrants, exiles, or refugees. They have suggested that the social, psychological, and cultural dynamics of ethnic group formation among forced migrants differ significantly from the dynamics among those who leave home voluntarily. In particular, forced migrants are believed to nurture especially strong connections to their homelands and to hope for their eventual return there. Such characteristics were central to the concept of the Jewish Diaspora.

In the past two centuries, scholars have recognized a limited number of other forced migrations—notably enslaved Africans in the sixteenth, seventeenth, and eighteenth centuries; Armenians threatened with genocide in Turkey after World War I; and displaced Palestinians—which have also been called diasporas. Occasionally, too, reference has been made to an Irish diaspora, the result of poor Irish farmers being forced from home by the devastating potato blight and the threat of mass starvation in the 1840s

*So many are the Genoese, scattered worldwide, that they build other
Genoas wherever they reside.* • **M. Bozzi (c. 1320)**

and 1850s. Nevertheless, for the most part it was the Jewish experience of exile, homelessness or statelessness, and attachment to a lost home that defined diaspora.

Jewish Diaspora

The destruction of the Temple of Jerusalem and the subsequent Babylonian exile became central to Jewish life, culture, and identity. Memories of this experience were passed from generation to generation, obscuring the fact that a significant contingent of early Jewish exiles restored the Temple in 515 BCE. At least since classical times, more Jews lived in scattered communities in Egypt and Anatolia (peninsular Turkey) than in the Jewish homeland around Jerusalem. The crushing of a Jewish revolt against the Romans in 70 CE, the second destruction of the Temple and a second

exile, and, somewhat later, Christian assertions about Jews' supposed role in the killing of Christ helped to solidify images of Jews as wanderers, persecuted wherever they traveled and never permanently settled anywhere.

In later periods, however, there is little evidence that the large populations of Jews living in the Catholic or Orthodox Mediterranean or in Muslim North Africa or western Asia were substantially more mobile than majority populations: most Jews settled permanently in cities. Their reputation for tenacious commitments and for emotional attachment to their ancestral homeland was in part a product of social and economic discrimination that prevented them from ever belonging fully to host societies, whether those societies were Catholic, Orthodox Christian, or Muslim.

Persecution sparked important Jewish migrations, especially between 1000 and 1500. In Catholic

Europe the Crusades heightened anti-Semitism; eventually, anti-Semitism led to the expulsion of Jews from Spain in 1492. Within the Muslim world, where Jews lived as constrained minorities in self-governing enclaves, trade may have motivated more Jewish mobility; certainly trade was one motivation for those Jewish merchants who first ventured into the Atlantic world and the Americas.

By the early nineteenth century, Jewish migrants resembled other central and western Europeans in traveling to the Americas in search of work, commercial advantage, or educational opportunity. Even later in the century, Jewish migrants to the United States were almost as likely to leave those countries that had begun to open opportunities for full citizenship to them as they were to leave places such as the Russian Empire, where the threat of violent peasant attacks (or pogroms) and levels of discriminatory practices in military service, schooling, and landownership remained very high.

Over the centuries, Jewish communities reached long-term and relatively peaceful accommodations with the Catholic, Orthodox, Protestant, and Muslim majority populations in the lands where they settled. When opportunities to return to their homeland opened with the creation of Israel in 1947, most Jewish North Americans did not choose to relocate. And thus, the vast majority of Jews still live in the

Diaspora. Nevertheless, memories of persecution and the possible necessity of renewed flight have been elements of Jewish life for millennia, elements that were reinforced by the horrific genocide—now termed the Holocaust—that occurred in Europe during World War II.

Armenian and African Diasporas

Like those of the Jewish faith, Armenians trace their exile to an early date. Armenians regard their homeland as Mount Ararat, a mountain in the east of present-day Turkey, near the border with Iran. There, according to the Bible, Noah's Ark landed and repopulated the Earth with people and animals. Armenians, whose Christian beliefs differed from those of their Orthodox rulers and neighbors, were first deported in large numbers in 578 CE to Macedonia, Cyprus, and other locations in the eastern Mediterranean, and subsequently most lived as minorities under the rule of Muslims. Armenians resisted conversion and, as traders, traveled far afield.

A revolutionary movement in pursuit of an independent Armenian state led to the murder of thousands of Armenians in the Ottoman Empire and the deportation of some 1.75 million Armenians in 1915. Perhaps half of the Armenian population either starved or were killed during the course of the

deportation. Of those who survived, many sought refuge in the Americas and Europe. Today about 2 million Armenians live in Europe, western Asia, and the Americas; roughly another 2 million live in the Central Asian republics of the former Soviet Union, and approximately 3 million live in an independent Armenian republic in their regional homeland.

If many Armenians stayed relatively close to their ancestral home, even when dispersed forcibly, an African diaspora formed far from the African continent—but primarily in the Americas. At least since the time of the Roman Empire, slave trading had scattered Africans across the Sahara and the Mediterranean and into the Muslim world of western Asia. After 1500, the numbers of slaves sent across the Atlantic to serve as laborers on plantations came to outnumber those sent elsewhere along older Old World slave routes. The culture and identities of Africans in the New World was a product of the complex intermingling of the customs of many African ethnic groups and of animist African, Muslim, and Christian religious beliefs. Separate African languages disappeared but contributed to the creation of hybrid pidgin dialects that blended African, English, Spanish, and Portuguese elements.

As African slaves in the Americas gradually acquired their freedom between 1830 and 1889, small numbers did return to Africa, notably to Liberia. But the much larger group remained in the New World, where they identified with biblical stories of Jewish captivity, exile, and longing for home. Many regarded Africa—and especially the independent nation of Ethiopia (not colonized by Europeans in the nineteenth century)—as the symbol of a lost homeland.

In the early twentieth century, the development of Pan-African movements among New World residents of African descent focused on ending European colonialism in Africa and racial oppression in the Americas. These movements linked activists in the Caribbean, the United States, and Africa. Even after the collapse of Europe's empires in Africa after World War II and the abandonment of legal and institutionalized forms of racial discrimination in the United States and South Africa, experiences of

racial prejudice continue to nurture an attachment to Africa among persons of African descent. Few have any intention of returning to Africa, however, even though the formation of independent African nations after 1950 made that option more plausible than ever before.

Recent Changes in Meaning

In a controversial development, scholars in recent years have begun to consider the possibility that other migrations, too, can create diasporas. In part, this change reflects scholarly appreciation of the difficulties of distinguishing definitively between forced and free migrations even in the African, Armenian, Jewish, Palestinian, or Irish diasporas. Scholars have acknowledged that elements of coercion and choice figure in the lives of most mobile persons. The willingness to use *diaspora* for analysis of a broader range of migrations also reflects the recognition that attachment to a distant homeland is not limited to exiles and refugees. The fact that many in the Jewish and African diasporas have shown little interest in returning to their ancestral homelands also suggests how problematic it is to distinguish vigorously among descendants of forced and voluntary migrants.

In the mid-1990s, the sociologist Robin Cohen sought to summarize changing use of the term by suggesting a typology of diasporas. Cohen distinguished between victim diasporas—such as the Jewish and Armenian diasporas—and those formed as people voluntarily left their homeland to look for work (labor diasporas), establish colonies (imperial diasporas), or engage in commerce (trade diasporas). Cohen encouraged scholars to debate the characteristics shared by all diasporas and to identify those characteristics that differentiated diasporas from other ethnic groups formed through long-distance migrations.

Trade Diasporas

At least since 2000 BCE, the desire for trade has encouraged merchants to form communities abroad without abandoning their loyalties or connections to their homelands and without abandoning their native

Italian immigrants living on Mulberry Street in New York City's Lower East Side jostled for space and economic opportunity with other recent arrivals, including Jews, Russians, and Austro-Hungarians (1900). Detroit Publishing Company, Library of Congress.

cultures. The ancient Minoans scattered throughout the Aegean, and the Phoenicians spread throughout the eastern Mediterranean. Greek merchants established colonies even more widely, especially in Sicily and western Asia.

In the years between 500 and 1500, Arab, Jewish, Armenian, and Genoese and Venetian merchants formed self-governing commercial enclaves in western Asia, around the Black Sea, in caravan towns through Central Asia, and along the coasts of Africa.

Similarly, Chinese merchants who lived in large numbers in many parts of Southeast Asia and the Philippines showed few signs of abandoning their Chinese culture or identity, and generally they intended to return home eventually. Most considered themselves sojourners in foreign lands, even if their communities persisted for centuries. After 1500, as European empire builders arrived in Asia, they often encouraged the expansion of Chinese trading communities because Chinese merchants served as effective cultural and economic mediators between the impossibly foreign-seeming Europeans and local populations and institutions.

In the modern world, trade diasporas continued to form. Lebanese traders from Syria scattered around

the Mediterranean and to North and South America during the nineteenth century. Many worked as peddlers before opening shops; in much of Latin America, Lebanese merchants played an important role in the creation of modern industries as well. Rates of return to Lebanon have been high, although as many as two-fifths of all the people who consider themselves Lebanese today live outside Lebanon. Although rarely analyzed as diasporas, the far-flung communities that U.S. multinational corporations create are self-consciously American and English-speaking. They often maintain considerable social and cultural distance from host societies and are viewed as unwelcome expressions of U.S. imperial power by local populations.

Imperial Diasporas

As in the case of the Greek Mediterranean two millennia earlier, mobile merchants often functioned as the vanguard of empire building in the European empires formed after 1500. Dutch, Spanish, Portuguese, German, French, and British colonists created settlements around the world that reproduced their own cultures rather than adapting the customs and languages of the natives among whom they lived.

Diasporas formed through empire building often had significant state support, with the government organizing, directing, and financing migrations of their citizens to strengthen some of their colonies demographically. From the seventeenth century onward, actions taken by the British state—land policies that forced poor Scots or Irish from their fields and crofts, the export of prisoners and children, sponsored migration of female spinsters—encouraged migration to its colonies, especially in Canada and Australia. Its military and government bureaucracies also organized the migration of soldiers, civil servants, and teachers to work in Africa, India, and other parts of Asia. While many so employed expected to return home again, and cultivated a pride in their Britishness that held them aloof from colonized populations, imperial migrants did sometimes also acquire an attachment to their new homelands and settle more permanently. This was true for colonialists from other European countries as well. In both French Algeria and British Rhodesia, settlers who had come as empire builders stayed on and violently opposed independence under native African rule after World War II, a fact that suggests the complex relationship between imperial culture, home, and host societies in imperial diasporas.

Proletarian or Labor Diasporas

The emancipation of slaves and the industrialization of cities in Europe and the Americas in the nineteenth century provoked vast new migrations that continued into the twentieth century. As many as 65 million Europeans migrated to the Americas, and as many as 40 million Chinese and Indians left their home countries between 1815 and 1930. Most of the Indian migrants and a substantial minority of the European and Chinese migrants traveled under some form of indenture, labor contract, or debt peonage. The so-called proletarian mass migrations are nevertheless considered voluntary. Workers followed the money in a global labor market that as often offered temporary and seasonal employment as opportunities for permanent settlement, especially by the latter years of the twentieth century.

Chinese, Indian, and southern and eastern European migrants were especially likely to consider themselves sojourners who intended to return home again. Perhaps as many as 90 percent of Chinese and Indian laborers returned from New World, Asian, or Africa plantations or mines. Among Italian laborers in agriculture and industry, rates of return were typically over 50 percent. Male laborers in all these groups left home, returned, and then departed again, often several times over the course of their lives. Recent research suggests that the constant circulation of mobile men, along with the often violently hostile reactions of native workers and host societies, reinforced sojourners' attachment to their homelands. Between 1880 and 1930, laws passed in Canada, the United States, and Australia to exclude or limit the migration of all contract laborers, to prevent the settlement of Chinese and Indians, and to limit the number of workers entering from Italy, Greece, and the Balkans had the same effect. The result was heightened ethnic and racial consciousness among even the descendants of workers who settled permanently abroad. Many have maintained distinctive ethnic identities and a continued awareness of their foreign origins over several generations. Some scholars now refer to these groups, too, as diasporas, although that labeling is controversial.

Migration, Ethnicity, and Diaspora

Few scholars would argue that every migration generates a diaspora. Many, however, accept a wider and more general application of the term than was common a half-century ago, when only forced migrations of victims were considered to create diasporas.

Scholars' extension of *diaspora* to cover merchants, laborers, and even empire builders may be the result of general scholarly unease with theories of assimilation and of ethnic group formation among the mobile. Since the 1930s, discussions of assimilation and the creation of ethnic groups have taken place mainly within the context of the history of immigration into countries such as the United States. In the past, it was

widely assumed that all migrants were immigrants who abandoned ties to their homelands, along with their ethnic identities, as they found full incorporation into host societies.

Discussions of multiculturalism in popular discourse, like scholarly broadening of the term *diaspora*, may have helped to point out positive elements of cultural pluralism and the persistence of ethnic identities among the descendants of migrants. Earlier assumptions about assimilation and its relation to human identity now strike many as too simple. Not only are individual identities understood to be more complex than was the case a century ago, but cultural diversity is now viewed more positively. In addition, recent theorists of transnationalism have suggested that the ease of travel and of communication in the contemporary world will likely facilitate the formation of diasporas among the 150 million migrants in today's world.

Nevertheless, recent studies of diasporas do suggest the usefulness of insisting on a number of shared characteristics that differentiate diasporas from ethnic groups generally. Most studies of diasporas, for example, focus on migrations that scatter in multiple directions, creating far-flung and rather extensive transnational social networks. As a result we find few references to a Mexican diaspora. However important and undeniable their ties to Mexico and the strength of their many transnational social and cultural activities, the vast majority of Mexicans over the past two centuries have migrated to only one country—the United States.

While ethnic groups may be temporary social formations among the migratory, diasporas maintain memories and sustain powerful myths about their homelands, which they typically idealize. These memories in turn generate dreams of a return to that homeland. Diasporas are thus characterized by strong group consciousness that is sustained over many years, generations, or even centuries. Diasporas typically have somewhat difficult relationships with the societies in which they make their homes, and their members typically maintain at least a minimal sense

of solidarity with their co-ethnics or coreligionists in other parts of the world. Diasporic consciousness also seems to be positively associated with cultural creativity; the distinctive music, art, or literature of a diaspora may be regarded positively by majority populations and at the same time may reinforce the sense of distinctiveness of those creating it.

In short, diasporas seem to be characterized not so much by the experience of forced migration as by a will to survive and to resist full assimilation into host societies, even when that option is open. A strong sense of shared history—often reinforced by experiences such as exile, persecution, or local hostility—can be reproduced over time within families, ethnic institutions, and through cultural production. This sense of shared history allows people in North America to feel a sense of solidarity with people of similar origins who may live in South America, Australia, Europe or Asia. Ultimately, then, diasporas are products of history. It is the passage of time that determines which mobile populations and which ethnic groups will become and remain diasporas.

Dictionaries and Encyclopedias

Dictionaries and encyclopedias are outgrowths of the human urge to decipher, systematize, explain, and learn. From cuneiform tablets to the World Wide Web, dictionaries have defined, standardized, and influenced the use of human language, while encyclopedias have mirrored and shaped knowledge.

During their long history, dictionaries have reflected the history and origins of language, in addition to offering definitions, etymologies, pronunciations, and spelling standards. But they have also been criticized for contributing to ethnocentrism and linguistic conformity. For their part encyclopedias have provided classification concepts to organize world knowledge, while simultaneously offering a snapshot in time of that knowledge. They have fostered learning by educating as well as edifying the reader. But encyclopedias have also been grounded in contemporary biases and superstitions.

Rudimentary forms of dictionaries and encyclopedias have been used since ancient times. Compilations of bilingual word lists began as early as 3000 BCE in Sumerian culture and were later adopted by their conquering neighbors, the Akkadians, who then spread them to peoples from other parts of the Middle East. The Western tradition can be traced to the Greek *glossai*, which were used to interpret the classic literary works of Homer and the ancient law (Green 1996). The concept of the *enkyklios paideia*, the “general” or “rounded” education, goes back to Plato and Aristotle. In fact the first recognizable “encyclopedia” work is considered to be a collection of Plato’s writings by his nephew Speusippos that were used for instruction at Plato’s Academy.

Dictionaries

In addition to the Greek *glossai*, there is an early tradition of lexicography in Sanskrit, as well as in Chinese, Arabic, and Japanese. As early as 300 BCE, lexicons were written to aid in understanding the Vedas, or sacred Hindu texts. Related to these is the later classic of Sanskrit lexicography, the *Amarakośha* by Amarasimha (650 CE). The Chinese tradition stems from early glosses like the *Erh-ya* in second century BCE. The *Shuo wen jie zi* compiled by Hsü Shen around 120 CE was the first etymological Chinese dictionary. While Arabic word lists and vocabularies predated it, the first Arabic dictionary is considered the *Kitab al’ Ain* by Al-Khalīl ibn Ahmad written in the late 700s CE. But it is the *Šihāh* by al-Jawhārī (d. 1003) that set the standard for the classic Arabic dictionary and the *Tāj al-‘arūs* by al-Murtadā al-Zabīdī (d.1791) that incorporated numerous previous works and represents the culmination of a thousand-year tradition. There is a long history of Japanese lexicography stretching from the Heian period (794–1185) to the end of the Muromachi period (1333–1573). The beginning of the modern Japanese dictionary, however, is traced to the *Rakuyōshū*, published by the Jesuits in 1598 (Bailey 1960).

Beside the Jesuit influence on Japanese dictionaries, there is an undeniable legacy of Western influence on non-Western dictionary making. Dictionaries of many African, Asian, and Pacific languages are relatively recent and bear the imprint of Western contact. Many of the first to study these languages and write dictionaries were missionaries and social workers. While making a significant contribution in being the first to record these languages,

Two pages of the *Yongle dadian*, the 11,095-volume encyclopedia commissioned by China's Yongle Emperor in 1403 (and completed by scores of scholars by 1408).

often their work was didactic and moralizing. In addition early missionaries like Alexandre de Rhodes compiled dictionaries using Romanized scripts, further portraying the native language through Western eyes. The same holds true for African languages with the later, more formal efforts of organizations like the International Institute of African Languages and Cultures, founded in London (1926), and the Instituto de Estudios Africanos, founded in Madrid (1939). And today, modern Arabic lexicographers, inspired by E. W. Lane's *Madd al-Qāmūs*, *Arabic-English Lexicon* (1863–1893), follow Western methods and principles.

Greeks and Romans

After the first century, Greeks and Romans continued building a tradition of lexicography. The famous Greek philologist Aristophanes of Byzantium assembled the first Greek dictionary entitled *Lexexis* (200 BCE) based on previous *glossai* and word lists. The prolific Marcus Terentius Varro contributed the *De Lingua Latina* (43 BCE) that was more a study of grammar, but with a number of etymologies. Other

writers like Verrius Flaccus (c. 10 BCE) and his *De Significatu Verborum*, Julius Pollux (180–238 CE) and his *Onomasticon*, and Photius (860–935 CE) and his *Lexicon*, also made their mark on early lexicography. Their work, and similar efforts, culminated in the great tenth-century lexicon the *Suda* or *Suidas*. Actually a combination dictionary and encyclopedia, the *Suda* contained about thirty thousand entries on language, literature, and history. More importantly, it integrated all of this material alphabetically. Up to this point, most works had not used alphabetical order (Collison 1964). Another later landmark was Ambrogio Calepino's *Dictionarium ex optimis quibusquam* . . . (1502), which came out in numerous editions into the early 1700s. Initially the *Dictionarium* was in Latin, but later expanded to a number of other languages including Hebrew, German, French, Greek, Italian, and English (Green 1996).

English Dictionaries

The first purely English dictionary was Robert Cawdrey's *Table Alphabeticall* [sic] in 1604. Consisting of only 2,560 entries, mostly plagiarized from

When I feel inclined to read poetry, I take down my dictionary. The poetry of words is quite as beautiful as the poetry of sentences. The author may arrange the gems effectively, but their shape and lustre have been given by the attrition of ages. • **Oliver Wendell Holmes Sr. (1809–1894)**

other sources, Cawdrey concentrated on so-called hard words. This “hard word” tradition held sway through the seventeenth century. Attempting to record all English words was left to the remarkable *Oxford English Dictionary* nearly three centuries later.

Dozens of other dictionaries were published after Cawdrey, but it was Samuel Johnson who authored the first great English dictionary. In a sense Johnson’s work was in response to the great continental dictionaries like those of Italy, the *Accademia della Crusca’s Vocabolario* (1612), and France, the *Dictionnaire de l’Académie Française* (1694). Johnson’s *Dictionary of the English Language* (1755) answered the need for an authoritative English language dictionary and “the growing desire to create . . . a national language” (Green 1996, 226). But instead of being a national project undertaken by an academy of scholars, the work was left to Johnson and six assistants. In all Johnson defined some 40,000 headwords, using approximately 118,000 quotations to support and differentiate meanings.

National impulses also inspired the work of Noah Webster. He realized that American English was distinct from the language spoken in England, and his *American Dictionary of the English Language* (1828) reflected this fact. His dictionary also had a lasting impact on the spelling of American English. But Webster’s work may have faded from view had not George and Charles Merriam purchased the rights from his family. The Merriams improved the quality of the dictionary and published revisions and abridgements on a regular schedule. The name Merriam-Webster is still one of the most respected in dictionary publishing.

The greatest of all English dictionaries is undoubtedly the fabled *Oxford English Dictionary*. The *OED*, as it is often referred to, was conceived as a recorder of actual historic usage, not as a standard, dictating proper English (Landau 1989). Under the editorship of the brilliant, if eccentric, James Murray, the first volume of the *OED* was published in 1884, with the final volume appearing in 1928. Since that time there

have been several supplements with a twenty-volume, second edition published in 1989. It is also available online and on CD-ROM, which allows quarterly updating. With its precise definitions, illustrative quotations, variant spellings, and comprehensive etymologies, the *OED* is an indispensable tool for the study of English.

Encyclopedias

The Romans laid the foundation of the written encyclopedia. The *Praecepta ad Filium* (184 BCE) by the famed Roman orator Marcus Terentius Cato (Cato the Elder) is considered the first extant written encyclopedia. Taking the form of letters to his son, the *Praecepta* is known to have included sections on “agriculture, medicine, rhetoric and possibly law and warfare” (Collison 1964, 23). Other similar works exist, but two particularly stand out. Marcus Terentius Varro (116–27 BCE) was an extraordinary scholar credited with seventy-four separate works in 620 volumes. His *Disciplinarum Libri Novem* devoted individual volumes to each of the seven liberal arts, as well as medicine and architecture, and foreshadowed the trivium (“the three roads”: grammar, rhetoric, and dialectic) and quadrivium (“the four roads”: mathematics, geometry, astronomy, and music) of later medieval education. Pliny the Elder’s *Historia Naturalis* (77 CE) consisted of thirty-seven books covering topics as diverse as metallurgy and the fine arts. In addition he was one of the first to cite his sources, and his work influenced encyclopedia making up to the Renaissance.

Eastern Traditions

The encyclopedia tradition is as rich in China as in the West. Although early Chinese encyclopedias also use classified arrangements, they are usually collections of significant prior works with dictionary elements. From the beginning these works were motivated by the need to educate civil administrators. The first Chinese encyclopedia appeared around 220 CE. It

Samuel Johnson, the author of the first great English dictionary, as depicted in Boswell's *The Life of Samuel Johnson*.

was entitled *Huang Ian* and was compiled by order of the emperor. Other early Chinese encyclopedias included the *Ch'u Hsüeh chi* (700 CE) and the more influential *T'ung tien* by Tu Yu (801 CE). The *T'ung tien* was the first of three works that formed the *San Tung*, which in turn was the foundation of a larger group of nine works published as the *Chiu Tung* in 1747 (Collison 1964). These encyclopedias collectively covered the prior twelve centuries and show

the tendency of the Chinese encyclopedias to grow and be augmented, rather than be replaced. Another example is the significant work *Yü-Hai*. Originally composed in 1267, it had evolved into a 240-volume collection by 1738. Throughout the 1600s there was a series of encyclopedias published under the auspices of the emperor with the highly illustrated *San ts'ai t'hu* being published in 1607–1609. The *Hsiao chih lu*, finished by Lu Feng-tso in 1804, was unique for its coverage of practical and technical matters. A number of other encyclopedias appeared later in the century with particular strengths in history, biography, and civil service. However, the first truly modern Chinese encyclopedia was the *Tz'u-yüan* published in 1915 and supplemented in 1931. In progress since 1982, the *Chung-kuo ta pai ko chuan shu*, well illustrated with lengthy articles, carries on the tradition.

Arabic encyclopedias also served the purpose of instructing civil servants, but in addition, they sought to inform the typical educated person. The first recognized work, the *Kitäl 'Uyün al Akhbar* by Ibn Qutayba (828–889 CE) was written with this audience in mind. Another significant Arabic contribution was the *Mafätih al-'Ulum* (975–997 CE) by the Persian scholar and statesman, al-Khwarizmi. Besides Arab influences, his work reflected an awareness of the more important Greek writings. Around the same time a religious and political party called the Ikhwän as-Safä published the *Rasä'il Ikhwän as-Safä* consisting of fifty-two pamphlets by five authors. (An edition of this work was published as late as 1889.) Later encyclopedias were published in Egypt, including the well-known *Nihäyat al-'arab fi funün al-adab* by an-Nuwairi (1272–1332), and the important and well-organized *Šubh al-a'sha* (1412), which was written for civil servants. The tradition of Arabic encyclopedias has continued into modern times with the works of Butrus al-Bustani (1819–1883) and his family. Their *Da'irat al-Maarif*, originally published in Beirut, has gone through three editions, the first published from 1875 to 1900 and the last finished in 1956. Today there are initiatives underway to publish major encyclopedias from the Islamic standpoint. A special

scholarly institute has been established in Iran and is at work compiling a multivolume encyclopedia to reflect the Shiite perspective.

Western Encyclopedias and the Church

The Western encyclopedia tradition felt Christianity's influence by the sixth century. Cassiodorus's two volume *Institutiones divinarum et humanarum lectionum* (560 CE) begins with chapters on scripture and commentary, as well as chapters on the historians and the Fathers of the Church. But Cassiodorus was also responsible for preserving the ancient Latin authors, pointing out "how to employ classical literature to support Christian education" (Katz 1998, 26). In his twenty-volume *Etymologiae*, Isidore of Seville (570–636 CE) shifts from the more narrow theological focus of Cassiodorus and emphasizes "the liberal arts and secular learning as the true basis of Christianity" (Collison 1964, 33). He tries to cover all that was then known of the world, even including an etymological dictionary.

The seeds of the medieval scholastic encyclopedia can be found in Isidore's and Cassiodorus's work. Scholasticism, which tried to reconcile ancient classical philosophy with medieval Church theology, was firmly rooted in later works. Hugh of St. Victor's *Didascalicon* (1120) is a noteworthy example. While adhering to the hierarchy of text placing scripture and Church-related subjects first, Hugh affirmed the seven liberal arts as the basis for classifying knowledge and insisted on the primacy of Latin, not the vernacular in his work. *Speculum majus* (1244–1260) is perhaps the most important of the medieval encyclopedias. Authored by Vincent of Beauvais, it consisted of nearly ten thousand chapters in eighty books and used some four hundred sources. The *Speculum majus* was still being referenced centuries after it first appeared. Unfortunately it also played a role in promoting anti-Semitism by containing a rewritten version of one of the best-known medieval anti-Jewish tracts, the *Dialogi contra Judaeos*, by Petrus Alfonsi. Around this time the *Hortus deliciarum* (1195 CE),

the first encyclopedia compiled by a woman, Herrad of Landsberg, appeared, as did the first encyclopedia in the vernacular, *Le Livre dou Tresor* (1265 CE), by Bruno Latini.

Renaissance to the Modern Era

The greatest contribution of the Renaissance was an encyclopedia that was barely begun and never finished; however, Francis Bacon's *Instauratio magna* (1620), with its proposed outline and classification scheme, was revolutionary and its influence lasting. Grounded in scientific method, Bacon covered every known topic of the day and his outline served as checklist for future encyclopedias, including that of Diderot and the great *L'Encyclopedie*. The seventeenth century also saw the popularizing of the alphabetical arrangement with the publication of Louis Moreri's *Le grand dictionnaire historique* (1674). This made the encyclopedia much easier to consult for specific facts. John Harris was the first to solicit experts to write articles for his *Lexicon Technicum* (1704). He also added high-quality illustrations and plates to his work, as well as selected bibliographies. Incorporating many of Harris's methods, Ephraim Chambers made the encyclopedia accessible to a mass audience by stressing readable articles in his *Cyclopaedia* (1728). He also broadened coverage of the arts and employed a through system of cross-references.

L'Encyclopedie and the Britannica

Denis Diderot and Jean le Rond, later known as d'Alembert, changed what started as a translation of the Chambers *Cyclopaedia* into what would become the most famous and storied encyclopedias in history. Under their guidance, particularly Diderot's, *L'Encyclopedie* (1765) became a revolutionary philosophical undertaking, featuring the writing of luminaries like Voltaire, Turgot, and Rousseau. It rejected much of the past, and it promulgated the scientific theories and advanced ideas of the Enlightenment. Reason, not the Church, was the source of

authority, and traditional learning was criticized for its prejudice and superstition. *L'Encyclopedie* was a powerful tool of protest and was subject to censorship and suppression. But because it also reflected the interests of the emerging middle class devoted to commerce and capitalism, it became widely popular and influential.

Two other names dominate encyclopedia publishing following the *L'Encyclopedie*: David Frederick Brockhaus and Pierre Larousse. Their works, the *Kversations-Lexikon* (1811) and the *Grand Dictionnaire Universel* (1876), featured short, accessible articles, alphabetically arranged, which highlighted their use as reference works to be consulted rather than read. Publishing houses bearing their names continue to publish highly respected encyclopedias today. Another great Continental encyclopedia that has to be mentioned is the *Enciclopedia italiana di scienze, lettere ed arti* (1929–1939). One of the finest national encyclopedias ever published, it is nonetheless international in scope (Collison 1964).

The *Encyclopedia Britannica* ranks in importance with Diderot's *L'Encyclopedie*. The first edition consisted of three volumes of both fact and fiction, but under the editorship of John Tytler that changed. His second edition (1784) was a ten-volume set with 340 plates and an emphasis on historical articles and biographies. It was revised and changed incrementally until the landmark ninth edition (1888), which along with the classic eleventh edition (1911) is thought the standard in balanced, accessible scholarship. These two editions created the *Britannica*'s reputation. But, the success of the *Britannica* was due to as much to marketing and an increasingly affluent middle class, as to the quality of the set, especially in the United States. By the fourteenth edition, released in 1929, the *Britannica* was being published in America and reflected American interests more than British. In the early twenty-first century, while still available in print, the *Britannica* is perhaps more commonly used in one of its electronic formats. There is a free version of the encyclopedia that gives brief excerpts from the full version, and a premium subscription with access full text and research tools.

Present and Future Trends

As knowledge grows exponentially, dictionaries and encyclopedias continue to evolve and change; they are no longer solely geared to scholars. Mass-market dictionaries and encyclopedias, appealing to a far wider audience, are available in supermarkets as well as bookstores. This is particularly true for dictionaries, and it heightens the tension between their proscriptive and descriptive roles. Dictionaries are asked to be authoritative yet neutral and objective, and at the same time describe living language as spoken by a broad population. This dichotomy can be expected to grow as dictionaries appeal to an even wider audience via computers and the World Wide Web. Some online dictionaries, like the free Dictionary.com, however, are gaining the trust of users by offering thorough and dependable definitions as well as keeping up with current words and terms.

Computer technology also provides timeliness undreamed of by previous dictionary makers. Online dictionaries can be updated immediately and continuously. In addition, computers revolutionize the way people search and retrieve needed information. As the editors of the *OED Online* note, "Complex investigations into word origins or quotations that would have been impossible to conduct using the print edition now take only a few seconds." And computers, combined with the World Wide Web, enable collaborative scholarly projects like the Digital Dictionaries of South Asia effort led by the University of Chicago, and popular collections of online dictionaries like yourdictionary.com.

Today the traditional role of an encyclopedia in classifying the world's knowledge is marginal. Indexes, cross-references, and hyperlinks supplant schema and classification. The encyclopedia is no longer read and contemplated; it is consulted for objective facts and background information. And the general encyclopedia is not the dominant form. There are hundreds of subject encyclopedias, including those like the *Grove Dictionary of Art* and Wiley-Blackwell's *Encyclopedia of Life Sciences*, that are larger than many general encyclopedias.

As with dictionaries, computers are accelerating the encyclopedia's transformation. Following the growing migration of information from print to electronic, dictionary and encyclopedia publishers are increasingly providing digital access to their content. Major publications like the *Oxford English Dictionary* and the *Grove Dictionary of Music* have moved online, and electronic collections of print reference works are being gathered in searchable databases like the Gale Virtual Reference Library, Oxford Reference Online, Credo, and Sage Reference Online, among others. Most of these publishers still offer print editions of their encyclopedias and dictionaries, but electronic access is a standard expectation among users. It is hard to ignore the advantages of a searchable database in which locating information is far easier and more flexible, and the results are immediate and easily accessible.

The most influential, as well as controversial development in the recent evolution of encyclopedias is the creation of Wikipedia. The Wikipedia (2010) website defines itself as "a multilingual, web-based, free-content encyclopedia project based on an openly-editable model [that] is written collaboratively by largely anonymous Internet volunteers who write without pay." The people at Wikipedia might have added that these volunteers "have no qualifying credentials save an Internet connection" (Chandler and Gregory 2010, 247). This lack of credentials on the part of the contributors is used to cast dispersions on the validity and reliability of Wikipedia. There are also complaints that "because of its open nature, it has also been subjected to vandalism," and that the "volunteers who write articles sometimes take excessive ownership of what they've contributed, deleting the changes, including corrections, that others make" (Goldsborough 2009, 13). While this is all true, there is no arguing with Wikipedia's success. As of April 2010, there were nearly 3.4 million articles in the English-language version alone, and according to Alexa (n.d.), a website specializing in Internet traffic metrics, Wikipedia ranks sixth among all websites visited on the Web. There have also been studies supporting Wikipedia's accuracy and reliability, the most

famous being an article appearing in the December 2005 issue of the prestigious journal *Nature*, which reported that Wikipedia "contains only slightly more inaccuracies in science-related topics than does *Encyclopaedia Britannica*" (Chandler and Gregory 2010, 248). The findings were disputed by *Britannica*, but nonetheless the impression among millions of users is that Wikipedia is useful for finding basic information and quick facts.

There can be little doubt that the advent of the World Wide Web and the availability of electronic information it provides have dramatically impacted the production and use of dictionaries and encyclopedias. Immediate access to useful information from respected publishers is readily available to libraries and individual subscribers willing to pay, while online communities of volunteers are producing free tools like Wikipedia that seriously challenge the place that traditional dictionaries and encyclopedias hold. But the computer and the World Wide Web also serve to further fragment information, violating one of the encyclopedia's original purposes: organizing knowledge into an understandable whole. The role encyclopedias have played in preserving knowledge is also threatened by the reliance on electronic formats that may not exist in coming decades. And the lack of standards inherent in World Wide Web publishing endangers the aura of authority and reliability attached to both dictionaries and encyclopedias. In short, the future holds both exciting promise and troubling pitfalls for these historically valuable reference works.

Diplomacy

Although ancient civilizations used emissaries and representatives in political negotiations, modern diplomacy began with ambassadorial practices in fourteenth-century Europe. Diplomacy has seen many different forms over the centuries, such as *raison d'état* and *realpolitik*, but the essential concept remains unchanged. Present-day diplomacy, known as summit diplomacy, will dominate the politics of the future and provide a meaningful role in the development of world organizations.

The term *diplomacy* refers to the conduct of relations between kingdoms, empires, states, and nation-states. Diplomacy has existed as long as humans have lived in organized societies. Early records from ancient civilizations around the world show that rulers regularly used emissaries to convey messages to one another and to negotiate agreements. But most historians would agree that modern diplomacy originated in Renaissance Italy.

Rise of Modern Diplomacy

During the fourteenth century the Italian city-state of Venice emerged as a major commercial power in Europe. The prosperity and strength of Venice depended on accurate knowledge of economic and political conditions in the states with whom the Venetians were trading. Venice stationed permanent representatives in foreign states in order to obtain reliable information. The Venetian system was quickly taken up by the other Italian city-states. During the Renaissance the Italian peninsula was divided into a number of city-states that engaged in constant

intrigue and bouts of warfare. The need for accurate information encouraged the stationing of agents, or ambassadors, in both friendly and rival states. The use of ambassadors then spread to the kingdoms of Western Europe. The constant stream of reports from ambassadors resulted in the creation of bureaucracies, tiny by modern standards, to process and collate information, and to send out instructions. By the early eighteenth century practically all the states of Europe had foreign offices in order to manage and administer their relations with other states. The head of the foreign office became known as the foreign minister, and foreign ministers soon became key members of the cabinets of all European states, wielding great power and influence. As diplomacy became increasingly systematized, various commentators began offering books of advice on the best way to conduct diplomacy. Niccolò Machiavelli's *The Prince*, first published in 1513, is only the most famous of many such volumes.

Early Practice of Diplomacy

Over the centuries many practitioners of diplomacy have left their mark on history. In the seventeenth century the French cardinal Richelieu, chief minister to King Louis XIII from 1624 to 1642, promoted a doctrine known as *raison d'état*, which held that the good of the state was supreme, and that diplomacy must be conducted free of sentiment, ideology, or religious faith. Alliances must be forged and broken with the interests of the state as the only guide. Contemporaries criticized Richelieu for his alleged lack of morality, but Richelieu replied that protecting the state was the highest form of morality. Richelieu

In 1868 China sent Anson Burlingame (center), a retired American diplomat hired by the Qing court, to head its first delegation to the United States. The resulting Seward-Burlingame Treaty most controversially welcomed Chinese immigrant labor to the U.S.

was enormously successful, and by the time of his death, France had emerged as the dominant power in Europe, a position it maintained for the next 170 years.

France's dominant position in Europe threatened other European states, however, leading to the creation of coalitions during the late-seventeenth and eighteenth centuries to contain French ambitions. Political observers and commentators of the eighteenth century, such as the Scottish philosopher David Hume, soon began to refer to the concept of the balance of power, under which states, acting in their own selfish interests, would create a balance, or equilibrium, in the state structure of Europe. The emergence in Europe of a network of states encouraged the growth of diplomacy.

Diplomacy in Asia revolved around the concept of a single strong state, China, ringed by tributary states, and the use of emissaries to maintain the system. The major exception occurred during the Southern Song dynasty (1127–1279) when central authority in China was weakened, and something approaching a balance of power emerged temporarily. The Byzantine and

Ottoman empires practiced a similar style of diplomacy under similar situations.

The Early Nineteenth Century

Following the brutality of the French Revolutionary and Napoleonic wars that began in 1792 and ended in 1815, a new style of diplomacy emerged. The Congress of Vienna, held from September 1814 to June 1815, was intended not only to divide the spoils of war but also to lay the foundations for long-term peace in Europe. The Austrian foreign minister, Prince Klemens von Metternich (1773–1859), masterminded what he hoped would be an enduring state system in Europe. The five major powers of Europe would exist in a balance of power. Rather than acting in their own interests and hoping that a balance would result naturally, they would act in concert, hence the use of the phrase “concert of Europe.” Self-interest would be put aside in favor of the larger good, according to Metternich. The larger good meant the supremacy of the conservative, authoritarian monarchies of Europe, and the struggle

A diplomat is a man who always remembers a woman's birthday but never remembers her age. • **Robert Frost (1874–1963)**

to suppress the new forces of liberalism and nationalism. Metternich favored an ideological approach to diplomacy. The Congress (or concert) system was maintained until the Crimean War of 1853–1856. Russia's defeat in 1856 resulted in its alienation from the concert system and ushered in fifteen years of instability in Europe.

Realpolitik

The years after the Crimean War saw the return of the idea that state interest had primacy in the conduct of diplomacy, a concept now known as *realpolitik*. But *realpolitik* was little different from the style of diplomacy conducted by Richelieu. *Realpolitik* had three prominent practitioners: Count Camillo Cavour (1810–1861), prime minister of the Italian state of Piedmont; Louis-Napoleon (1808–1873, also known as Napoleon III), emperor of France; and most notably, Otto von Bismarck (1815–1898), who served first as chancellor of Prussia, and then later of Germany. All three made and broke alliances, commitments, and understandings according to the ever-changing needs of the state. Their actions frequently appalled contemporaries, but the good of the state was the primary consideration for those who conducted *realpolitik*. Count Cavour was successful in leading the campaign for Italian unification before his premature death in 1861. Louis-Napoleon was less competent, and met military defeat and humiliation in war with Prussia in 1870. Louis-Napoleon's nemesis was Bismarck, the most successful diplomat of the nineteenth century. Bismarck orchestrated the creation of a unified Germany under Prussian leadership in 1871. France had been sidelined, and Germany was now at the center of European diplomacy.

The Later Nineteenth Century

Having successfully orchestrated the unification of Germany despite intense pressure both domestically and from other European states, Bismarck was now determined to maintain its central position in Europe.

Bismarck feared that Germany was surrounded by potentially hostile states. He established a complex network of alliances designed to ensure that France remained isolated and that the other leading powers of Europe remained bound to Germany in some way. European diplomacy after 1871 was dominated by Bismarck's alliances and the need to maintain them. Bismarck demonstrated great skill in doing so. He maintained that Germany was a "satiated" power and could act as an honest broker in disputes between powers. In 1884, for example, Bismarck hosted the Berlin Conference, which set the ground rules for European expansion into vast areas of Africa and Asia. European diplomacy always had an impact on the peoples of North and South America, Africa, and Asia in the late nineteenth century. European powers fought not only in Europe, but also for advantage in overseas possessions and territories. But the Congress of Berlin was the most dramatic illustration of the global impact of European diplomacy up to that time. During the nineteenth century attempts by European powers to subjugate Asian and African states became known as "gunboat diplomacy," or "coercive diplomacy."

Bismarck left office in 1890. His successors were much less skilled in maintaining his alliances. By 1914 Germany was surrounded by an alliance system known as the Triple Entente, which included Britain, France, and Russia. As a result, Germany headed the Triple Alliance, along with Austria-Hungary and Italy, but Italy remained neutral when war broke out in 1914.

It is common to refer to the nineteenth century as the era of classical diplomacy. Diplomats of all European countries came from similar social backgrounds, usually the aristocracy, shared many common assumptions, and conducted diplomacy largely free from the impact of public opinion and domestic lobby groups.

The New Diplomacy

The trauma of World War I, with 9 million dead, led many to condemn what they referred to as the

“old diplomacy,” by which they meant diplomacy conducted by professionals. Allegedly the diplomats, acting often in secret, had created a network of alliances that plunged Europe into a horrific war. In 1918, U.S. president Woodrow Wilson (1856–1924) emerged as the leading spokesman for the “new” diplomacy. Wilson argued that diplomacy should be conducted in the open, and that “open covenants” should be openly arrived at. Instead of secret alliances, Wilson advocated the creation of a League of Nations so that the rule of international law would replace the anarchy of the prewar years. Instead of going to war, nations would submit disputes to the League for resolution. Aggressors that ignored the League would face economic sanctions and possibly military action. Some of Wilson’s ideas were implemented in the Treaty of Versailles that ended World War I. The Treaty of Versailles contained the charter for the newly created League of Nations.

Wilson, a liberal internationalist, introduced ideology once again into the conduct of diplomacy. Vladimir Lenin, who led the Bolsheviks to power in Russia in 1917, challenged Wilson’s ideas. As a Marxist, Lenin wanted to transform the war between nations and empires into a class war. His newly appointed commissar for foreign affairs, Leon Trotsky, said that he would issue a few proclamations, then close up shop. Once the worker’s revolution had swept away the old order, the need for diplomacy would vanish. The Bolsheviks also published secret documents drawn up by the Allies during the war for the partition of the Turkish Empire, further discrediting the old diplomacy. By 1921, however, it was clear that the worker’s revolution had succeeded only in the Russian Empire, renamed the Union of Soviet Socialist Republics (USSR). Lenin’s successor, Josef Stalin (1879–1953), had to maintain the security of the Soviet state, which required a great deal of diplomacy.

Adolf Hitler (1889–1945) came to power in Germany in 1933 determined to destroy the Versailles system. Hitler wanted Germany to obtain *Lebensraum*, or living space, in Eastern Europe, and did not shy away from the use of war to achieve his goals.

Hitler found the traditional mechanism of German diplomacy wanting, and he pushed aside professional diplomats in favor of Nazi party appointees such as Joachim von Ribbentrop, German ambassador to Britain in 1936 and, after 1938, Nazi foreign minister.

By the mid-1930s the unity that held nineteenth-century diplomacy together had fractured. Diplomats were divided by ideological differences and increasingly came from differing social backgrounds. Public opinion exerted an unparalleled influence on diplomacy. The League of Nations Union, formed to ensure that the British government followed League principles in the conduct of its foreign relations, attracted tens of thousands of followers in Britain. The old diplomacy had virtually ceased to function. Following the Italian invasion of Ethiopia in 1935, the foreign ministers of France and Britain—Pierre Laval and Samuel Hoare, respectively—attempted to make a secret deal with Italian dictator Benito Mussolini to end the crisis. Such dealings would have been routine in the nineteenth century. However, details of the agreement, which would have given Mussolini most of Ethiopia, were leaked to the press, forcing the resignations of both Hoare and Laval.

Summit Diplomacy

The approach of war in 1938 saw the emergence of summit diplomacy. Heads of state had been expressing frustration with what they felt was the plodding pace of diplomatic activity. Soon after taking power, Neville Chamberlain (1869–1940), prime minister of Britain from 1937 to 1940, said that he wanted to “stir up” the British foreign office. Modern communications and transportation meant that leaders could conduct their own diplomacy, and no longer had to rely on professionals. In September 1938, Neville Chamberlain flew to Germany three times to meet with Hitler in a bid to defuse the crisis over Czechoslovakia. Chamberlain’s actions created a sensation at a time when air travel was still the preserve of the wealthy elite. Chamberlain’s efforts proved futile, but face-to-face

meetings of leaders, known as summit diplomacy, proved an enduring innovation. The Allied leaders met repeatedly during World War II to coordinate their efforts. Summit meetings between presidents of the United States and Soviet leaders became a regular feature of the Cold War. During the early 1970s the constant movements of United States secretary of state Henry Kissinger between Middle Eastern capitals, in an attempt to resolve the Arab–Israeli conflict, gave rise to the phrase “shuttle diplomacy.”

Diplomacy in the New Century

Summit diplomacy remains the preferred form of diplomacy for world leaders at the dawn of the twenty-first century. Foreign ministries continue to debate foreign policy issues and offer advice to heads of state. Ambassadors are less important than in the past, but they still play a key role in the functioning of diplomacy. Summit diplomacy will continue to dominate the future of diplomacy, especially as it presents world leaders in a positive light. But diplomacy will also increasingly function in the context of international multilateral organizations such as the North Atlantic Treaty Organization (NATO), the G-7 concert of the world’s economic powers, the European Union, and the United Nations.

Diseases—Animal

Every disease that has caused epidemics and changed the philosophical traditions of societies throughout human history has originated in nonhuman animals and “jumped the species barrier” into humans. There is no meaningful separation between animal and human diseases when discussing the impact of disease on human history.

It is important to emphasize that because humans are mammals, diseases found in other nonhuman animals, especially other mammals, often cross readily into humans. The most important diseases are infectious and highly contagious. Noncontagious diseases have had little or no impact on history. By definition, infectious diseases are capable of spreading rapidly from infected to healthy individuals. Infected individuals either die or recover fully within a short period of time; those individuals who recover typically acquire immunity against further infection by the same illness.

Numerically, the single greatest documented epidemic in human history was an influenza outbreak that killed 40 million people at the end of World War I. The epidemic with the greatest recorded impact was the bubonic plague that killed over 25 percent of the people in Western Europe in the mid-fourteenth century. Despite a lack of documentation, however, the epidemics with the greatest overall impact both on human populations and history were the series of outbreaks that spread through the Americas shortly after contact with Europeans and their domestic animals. These epidemics spread through populations previously unexposed to the diseases of Eurasia, typically

causing 90–95 percent mortality, especially within communities suffering from multiple traumas associated with colonialism—violence, slavery, subsistence collapse. Overall these diseases may have killed as many as 100 million people in the Americas.

Prominent examples of infectious diseases that have crossed from other animals into humans include smallpox, cholera, tuberculosis, bubonic plague, and influenza. Although AIDS represents a major potential health problem in the modern world, it is contagious, but neither infectious nor acute. In recent years there have been panics over other animal diseases such as hoof-and-mouth disease, Hanta virus, and so-called mad-cow disease, which may not be a disease in the usual sense at all. These pathological conditions are trivial compared to the impact of the other diseases listed, yet they have received more publicity, perhaps because of ignorance and media-inspired fear, combined with the fact that most people do not understand how various diseases are transmitted.

Most infectious animal diseases that jump to humans are caused by bacteria and viruses whose small size renders them highly volatile and transmissible as aerosols, hence more likely to be transmitted from one individual to another, which is the basis of contagion. A few diseases, such as malaria and sleeping sickness, are caused by protistans, single-celled eukaryotic organisms that are much larger than bacteria or viruses. The larger size of protistans means they cannot be transmitted as aerosols, and hence are transmitted primarily by injection, for example, through insect bites, rendering them much less infectious.

Most infectious disease organisms co-evolve in interactions with other nonhuman species. These

Lithograph by Marlet.

nonhuman species have evolved an immune response to the disease-causing organisms, so they are not serious threats either to health or population numbers in their original host species. What renders most of infectious diseases so virulent in human populations is that when first exposed, humans have no evolved immune response to these pathogens; for example, smallpox is related to bovine pox, which causes minor problems in cattle but is often fatal in its mutated form in humans. Similarly, the AIDS virus is closely related to a viral infection that occurs in African primates, where it only causes mild influenza-like symptoms. Other examples include measles, which is closely related to the ungulate disease rinderpest; tuberculosis, which is closely related to a similar disease in cattle; and influenza, which is actually a complex of viral diseases derived repeatedly from similar pathogens occurring in pigs (swine flu) and birds such as ducks and chickens. Recently, malaria was added to this list when it was discovered that the human malarial parasite is closely related to a less virulent form in chimpanzees.

Contagious diseases that manage to cross the species barrier from nonhumans into humans have been a major factor shaping the history of Europe and Asia. A major difference between Europe and Asia as contrasted with the Americas and Africa is that

Eurasian cultures domesticated and lived in close association with the animal species that served as the original hosts of these diseases. Domestication of ungulates, especially cattle and swine, set up scenarios whereby humans living on intimate terms with these animals were continually exposed to a wide range of epidemic diseases, which already afflicted the ungulate populations as minor problems. These diseases thrived particularly well in the high densities at which human societies kept cattle and pigs. Farmers are sedentary, living among their own sewage and that of the domestic animals with whom they live in an intimate and symbiotic fashion. In many agrarian societies farmers traditionally took cattle and pigs into their homes at night, both for warmth and to protect their livestock from predators. These conditions both prolong exposure and increase the likelihood of transmission of bacterial and viral pathogens.

Agriculture sustains much higher human densities than the hunting-gathering lifestyles that agriculture replaced. The large concentrations of humans resulting from increased urbanization provided fertile ground for the rapid spread of infectious diseases that originated in other species. Only within the last century did European cities achieve self-sustaining populations, because so many city dwellers died from

disease that constant immigration from rural areas was required to sustain urban areas.

The Black Death

Development of world trade routes rapidly increased the dispersal rate of epidemic diseases. By Roman times the populations of Europe, Asia and North Africa had become a giant breeding ground for disease organisms that originated in domestic livestock. Smallpox reached Rome in the second century CE, killing millions of Roman citizens as the Plague of Antoninus. The animal-borne disease with the most profound impact on the course of history in Europe and Asia was bubonic plague. Spread by fleas that pick up the plague bacillus from the fur-bearing mammals that are their normal hosts, plague first appeared in Europe as the Plague of Justinian in 542–543 CE. The most devastating impact of the plague, however, occurred in fourteenth-century continental Europe where it killed as many as 25 million people and became known as the Black Death. In the British Isles alone, plague killed nearly 1.5 million people (25–40 percent of the total population). The main vector for the major outbreak of plague appears to have been furs brought from low-population density areas in central Asia with the opening of trade routes to China in the mid-fourteenth century.

One important, often unappreciated, consequence of the fourteenth-century plague was its profound impact on European philosophy and science. The prevailing European worldview prior to the mid-fourteenth century was mythic and symbolic, rooted in an idea of cyclical time, placing far more emphasis on links between human and nonhuman aspects of the world than did the worldviews that arose after the Black Death.

When plague arrived and began to have devastating impact on local populations, the knowledge base and techniques of this older philosophical tradition were pressed into service, including prayer, medicine based on sympathetic magic, and scapegoating (for example, witch burning). None of these

methods proved effective, and the inability to deal with the resulting death and devastation created both widespread panic and subsequent culture-wide depression. The impact of massive, inexplicable loss of life on a society cannot be overestimated. Belief in spiritual traditions and ways of understanding how the world works are crushed, leading to a sense of spiritual desolation.

The experience of the plague, described by some historians as the “greatest biological-environmental event in history” and the “equivalent of nuclear holocaust” by others, forced Western Europe to develop a new way of organizing its perception of reality. Within Christianity the plague led to loss of faith in a benevolent, heedful Creator, leading to persecution and scapegoating of “heretics,” eventually leading to the beginnings of Protestantism and its images of a vengeful, wrathful God.

From a more scholarly perspective, response to the plague experience led to development of an intellectual tradition that separated mind from body, objective from subjective, and human from nature. This led to the beginnings of the Renaissance and development of the Western European “rationalist” scientific tradition, ultimately generating Cartesian dualism, the machine model/metaphor as a way of understanding nonhuman life, and the Baconian-Newtonian worldview. Thus the philosophical and spiritual impact of plague led directly to the “modern” rationalist approach in which experimentation and measurement substituted for observation and experience.

This new way of dealing with reality had numerous positive effects. For example, it led to increased sanitation, which reduced background levels of many contagious diseases. This division of reality into separate spheres of mind and matter provided a powerful methodology for the study and understanding of the “outside” world. It was largely inadequate, however, for understanding inner experience, the human mind, and our relationship with the world of our fellow life forms. Thus, although this dualistic view led to improved sanitation, there was no increased

understanding of the natural cycle of disease or the evolution of immune responses.

Old and New Worlds

The importance of animal diseases in shaping both human history and cultural attitudes toward the environment can be illustrated by comparing the Old World (Eurasia and North Africa) with the New World (North and South America). Many cultures in the Americas developed agriculture, but New World agriculture was based almost exclusively around agronomy, for example, corn, potatoes, squash, and beans, rather than on pastoralism, the herding and domestication of ungulates. The only domestic animals in the Americas were dogs, guinea pigs, guanacos (llama and alpaca), and turkeys. Unlike the domesticated ungulates of the Old World, these New World domesticates were never maintained at high densities, humans did not drink their milk, nor were any of these animals except dogs kept in close proximity to humans, as were livestock in the Old World.

Many New World cultures existed at densities comparable to those found in Europe. The Aztec capital of Tenochtitlán may have been one of the largest cities in the world during its heyday, and there is evidence that in central Mexico human populations surpassed the long-term carrying capacity of the land. Similarly, many other New World communities such as cities of the Mayans, Incas, and the Mound Builder cultures along the Mississippi and Ohio River valleys, lived at densities comparable to those found in European and Asian cultures. Despite high population densities, however, epidemic (crowd) diseases appear to be virtually nonexistent in these indigenous New World cultures; this is almost certainly attributable to the absence of domestic ungulates which have been the source of most epidemic diseases (other than bubonic plague) in Europe, Asia, and North Africa. Despite the apparent absence of epidemic diseases in the New World, such diseases may have played a role in the disappearance of some of the larger city complexes in the Americas, possibly because of poor sanitation.

New World Animal Diseases

One of the greatest ironies of the history of animal diseases is that the absence of nonhuman-derived contagious diseases and associated immune responses in New World humans was almost certainly the major factor in the successful invasion of the New World by Europeans and their worldview, which had been dramatically reshaped by their own experience with contagious disease only a few centuries earlier. Europeans sometimes occupied large parts of Africa and Asia, but without the decimating impact of introduced contagious diseases, they did not significantly reduce the indigenous human populations of these areas. As a consequence, as the age of colonialism draws to a close, the indigenous peoples of Africa and Asia have been able to regain social and political control of their own lands because they have remained numerically dominant in their homelands.

In contrast, the introduction of animal diseases into susceptible human populations in the Americas was much more devastating to indigenous human populations than it was during the plague in Europe. It is estimated that 90–95 percent of the indigenous human population of the Americas perished from introduced diseases.

Contrary to popular mythology this holocaust—referred to as the first, or microbial, phase of the European conquest of the Americas—did not begin with the “discovery of the Americas” by Columbus in 1492; it was initiated some time earlier by Basque whalers, Viking settlers, and English fishermen who began landing along the Atlantic coast of the Americas hundreds of years before Columbus arrived in the Caribbean and before other Spanish explorers (conquistadors) arrived in the New World. There is evidence that some tribes originally living along the Atlantic Ocean retreated inland in an effort to escape epidemics that devastated their populations well before the arrival of Cristóbal Colón at the end of the fifteenth century.

Despite the success of supposed conquistadors like Cortez and Pizarro, it was smallpox that really led to the collapse of the Aztec and Inca empires. Cortez’s

“The Wonderful Effects of the New Inoculation!” by J. Gillray. Cow Pox (better known today as smallpox) decimated the indigenous populations of North and South America when European explorers introduced the disease.

initial 1519 foray into the Aztec civilization was much less successful than his subsequent 1520 effort after smallpox arrived in Tenochtitlán. By the early seventeenth century the indigenous population of Mexico had experienced devastation exceeding 90 percent, falling from an estimated 20 million to less than 2 million. The impact of the disease was demoralizing and crushed the ability of the Aztecs to resist Cortez. Similarly smallpox arrived in Inca territory in 1526, setting up the opportunity for Pizarro’s successful “invasion” in 1531.

There is recorded evidence that 90 percent or more of the indigenous populations were wiped out by these new contagious diseases that arrived with both Europeans and their symbiotic nonhumans. In one well-documented example, the Mandans, one of the most elaborate of the Great Plains cultures, more than 95 percent of their population died after the arrival of smallpox via a Missouri riverboat in 1837.

Even given these impacts, however, it is likely that New World populations would have rebounded had their land not remained permanently occupied after European invasions and the subsequent continued colonialism that resulted.

The introduction of alien diseases had a devastating impact on the indigenous peoples of the Americas. If the deaths of 20 to 40 percent of local populations in Europe as a result of plague caused restructuring and rethinking of the role of humans in the world, it is difficult to imagine the spiritual, social, and philosophical impact of the loss of 90 to 95 percent of a population, as occurred in many indigenous peoples of the Americas.

Disease is a major factor in limiting rates of population growth; in fact populations free of the impact of diseases typically outstrip those subject to disease. Indigenous Americans appeared relatively free of epidemic disease prior to the arrival of Europeans.

As a consequence indigenous populations had not evolved any immunity to contagious diseases. They did not lack the ability to produce immune responses; instead, the devastation appeared to result from the way in which indigenous populations were exposed to contagion. The major killers of indigenous Americans—smallpox and influenza—were lethal to persons primarily from fifteen to forty years of age, hence the most valuable and productive members of a population, both culturally and demographically. These diseases typically arrived in clusters, punctuated by brief interludes of respite. Thus communities might be ravaged by a series of three or four diseases, followed by a period of remission; communities might subsequently be hit by another bout of a new disease or set of diseases. This combination of periodicity of events with the plurality of the diseases reduced the ability to evolve immune responses.

This pattern generated extreme psychological and spiritual stress. Unable to prevent disease or care for themselves or loved ones, abandoned by kin and other tribal members fleeing the epidemic (and in the process often carrying it to other peoples and communities), many individuals and groups simply gave up hope. Many engaged in activities that only hastened their deaths, such as sweats followed by immersion in cold water. The inability of their traditional holistic methods to treat diseases and control these contagions caused them to lose faith in their healers and medicine people and also to abandon traditional spiritual practices and ceremonies. Because the European invaders had developed some immunity to these diseases, many indigenous peoples assumed that European spiritual and philosophical traditions were superior to their own, which in many cases led to acceptance and adoption of Christianity and its tenets.

The apparent failure of indigenous spiritual traditions, combined with the introduction of new goods and materials, led indigenous peoples to abandon centuries-old traditions of dealing with the natural world, which were based on respect, connection, and conservation. Some peoples may even have blamed the wildlife and the natural world for the epidemics,

because it appears that many indigenous peoples associated disease with wildlife and developed cultural traditions that were assumed to minimize the likelihood and impact of disease. For example, the Cherokee assumed that disrespectful treatment of killed deer could lead to crippling illness, such as Lyme disease, which produces crippling effects. The Cherokee blamed the appearance of new diseases on an imbalance in the cosmos caused by failure on their part to perform their rituals correctly. Similarly the Anishinaabe (Chippewa, Ojibway) peoples apparently developed the Mediwiwin healing society and related ceremonies in response to diseases they associated with wildlife, but the diseases were more likely the results of pre-Columbian contact with Europeans.

Affect on Nonhuman Species

Not only humans suffered as a result of the introduction of these diseases. Indigenous peoples depended on many natural populations of animals as sources of food and clothing, including deer, caribou, moose, bison, and beaver, that also experienced massive die-offs from west of Hudson Bay to the Rocky Mountains during the latter part of the eighteenth century. These deaths probably resulted from disease introduced by Europeans through their domestic animals. It is worth noting that these die-offs were primarily among ungulate populations, which would have been most susceptible to the ungulate-borne contagious diseases characteristic of Europe and Asia. New World carnivores, such as wolves and bears, appeared relatively unaffected by these illnesses, but they suffered as a result of the loss of their ungulate food supplies.

In addition to the impact of disease, additional damage was inflicted upon natural populations of animals when indigenous people destroyed animal populations because of an apparent antipathy towards animals, whom were assumed to have broken their covenants with humans by infecting them with disease. Thus one ironic consequence of the introduction of nonhuman-derived diseases was the destruction of cultural traditions based on respect for nonhumans. Most, if not all, indigenous cultures of

North America had philosophical traditions where nonhumans were regarded as creator spirits, and the concept of relatedness was based upon ecological relationships. It has been argued that the devastating impact of introduced disease on these cultures caused them to turn on their nonhuman relatives, allowing some tribes to wipe out local populations of beaver, deer, bison, and wolves, in order to trade furs for European goods and metal.

European Tradition and the Natural World

The invading European tradition, derived primarily from English and Scots cultures, had a very different relationship with the natural world, especially as a result of the Renaissance and the rationalist tradition, which worked to separate itself from any association with the natural world, except as a resource for exploitation. Protestant Christian sects that appeared in western Europe towards the end of the Renaissance (during the Reformation) developed philosophical traditions that offered no encouragement for investigation into the ways of God's creatures. God had given humans "dominion" over nonhumans, providing sufficient justification for any action regarding the natural world.

Europeans regarded mountainous country as unpleasant and dangerous, and forests were considered to be even worse. That these places were wild, hence untamed, was sufficient to trigger terror and hostility in western Europeans. The wild (natural world) was so unreasonably fearsome that encroachment of wild creatures into the human domain was highly alarming. A bee flying into a cottage or a bird rapping at the window was enough to frighten people. The English House of Commons rejected a bill in 1604 because a jackdaw flew through the chamber during the speech of its sponsor.

This difference in response to the nonhuman (natural) world continues to manifest itself today in contemporary responses to animal-borne disease. These responses are often extreme in comparison to the actual threat. The most egregious response in recent

years has been the slaughter of hundreds of thousands of farm animals, particularly in the British Isles, in response to minor outbreaks of hoof-and-mouth disease and the sporadic and highly unusual occurrence of so-called mad-cow disease.

In the case of hoof-and-mouth disease, the threat is almost exclusively economic. There is little evidence that hoof-and-mouth disease represents any serious threat to human health. Still the economic threat is deemed sufficient enough to destroy hundreds of thousands of animals, mostly because the possibility exists that they may have been exposed to the disease. Can any moral being imagine such a draconian solution if the animals exposed to a potential contagion were *Homo sapiens*, rather than ungulates? Similarly, wild bison that stray beyond the borders of America's Yellowstone National Park are summarily slaughtered by agents of the state of Montana on the grounds that these animals might act as reservoirs for the cattle disease brucellosis. The irony in this case is that brucellosis is a disease that evolved in Old World bovids and was introduced into America along with cattle. No bison has ever shown the symptoms of brucellosis, yet the fact that a low percentage of bison test positive for exposure to the pathogen is deemed sufficient reason to kill them.

The response to mad cow disease, more properly called bovine spongiform encephalopathy (BSE), is even more absurd. BSE appears to be one of a group of related pathological conditions that may be caused by prions that appear to be protein molecules capable of self-replication. Other diseases in this category are scrapie in sheep and both kuru and Creutzfeldt-Jakob disease in humans. Such pathological conditions impact the central nervous system (CNS) and gradually destroy the brain. The damage to the CNS is what produces the symptoms that have disrespectfully led to this condition being designated with the term *mad cow*. A far better and more accurate term would be *acutely distressed cow*. These apparently prion-based conditions are not directly communicable and can only be passed through consumption of CNS tissue including brain and spinal cord. The only reason these conditions appeared to spread in the United States and

England is because slaughterhouses in those countries use “wastes” remaining after butchering to be ground up and added to cattle feed as a protein supplement.

In humans it is obvious that only through consuming CNS material can humans become infected. Outbreaks of kuru in New Guinea are clearly related to the cultural tradition of consuming the brains of other humans as part of a cannibalistic tradition. In England, BSE-type syndromes have shown up in humans who consumed low-grade commercial hamburgers. It seems obvious that banning the use of the waste products of slaughterhouses in both hamburger for human consumption and in cattle feed could stop any possible outbreak, yet commercial pressures have slowed or prevented such moves. Still, the total number of BSE human victims numbers less than twenty, and there is little likelihood of an outbreak or of a human contracting BSE through eating regular beef in the form of roasts or steaks.

Hanta virus is a rodent-borne viral pathogen. There is actually an entire class of Hanta-like viruses in a variety of murid rodents. The one described as Hanta virus appears to have only one species—deer mice, or *Peromyscus maniculatus*—as its primary host; it does not appear to cause significant health problems in deer mice. In humans, however, this virus causes pneumonia-like symptoms that result in death about 50 percent of the time. This disease is well-known to indigenous peoples of the American Southwest and may be one of the reasons that traditional Diné (Navajo) people destroy a hogan after a person has died in it. In recent years this disease has caused a minor panic in the United States because deer mice are a widespread, common rodent. Hanta does not appear

to be transmissible among humans, so it is unlikely to ever become a true epidemic. The number of recorded cases in the United States is less than two hundred since the Center for Disease Control (CDC) has been keeping records.

The major environmental and health-related problems in humans result primarily from close association with domestic animals. This continued proximity has allowed several diseases to jump from their ungulate or avian hosts and cross the species barrier into humans.

Diseases—Overview

The study and treatment of disease is a never-ending pursuit due to human evolution and our ability to adapt to and resist diseases over time. Research shows that disease increased as foraging stopped and humans began settling together in one place. Only in the twentieth century did epidemiologists recognize that hosts and germs adjust to one another, so symptoms (and medical diagnoses) change.

Disease refers to many kinds of bodily malfunction: some lethal, some chronic, and some merely temporary. Some diseases, like cancer and Alzheimer's disease, increase with age and result from disordered processes within our bodies; others arise from infection by invading germs and afflict children more frequently than adults because we develop immunities after early exposure to them. Symptoms of infectious diseases vary with time and place, owing to changes in human resistance and to evolutionary changes in the germs themselves. Consequently, written descriptions of ancient infections, even when quite detailed, often fail to match up with what modern doctors see. Hence, even when records exist, determining exactly when a particular infection first afflicted people in a given place is often unknowable. And no one can doubt that major disease encounters also took place among peoples who left no records for historians to examine. Nonetheless, and despite all such difficulties, some landmarks in the history of the human experience of disease are discernible from the deeper past, while in recent times the changing impact of diseases and medical efforts to control them are fairly well known.

Diseases among Foragers and Early Farmers

It is safe to assume that our remote foraging ancestors encountered many sorts of parasites, some of which, like the organism that causes malaria, were seriously debilitating. Sleeping sickness, spread by tsetse flies, was so lethal for human hunters that parts of east Africa remained uninhabited until recently, thus preserving vast herds of game animals that tourists now come to see. All the same, it is probable that our early ancestors were tolerably healthy and vigorous most of the time. That, at any rate, is the case among surviving African foragers as observed by modern anthropologists. Probably infectious organisms and their human hosts were fairly well adjusted to one another, having evolved together in tropical Africa; diseases of aging scarcely mattered since their lives were far shorter than ours.

Since many of Africa's tropical parasites could not survive freezing temperatures, infections probably diminished sharply when human bands expanded their range, penetrating cooler climates and spreading rapidly around the entire globe. Leaving African infections behind presumably increased human numbers and helped to sustain their extraordinary geographic expansion.

But infections began to increase again when, in different parts of the Earth, a few human groups began to cultivate the soil and settled down in the same place all year round. That was partly because food production allowed more people to crowd together and exchange infections, and more especially because supplies of water were liable to become contaminated

Pieter Bruegel, *The Triumph of Death* (c. 1562). Oil on panel. The painting reflects the social upheaval and terror following the bubonic plague that devastated medieval Europe.

by bacteria from human wastes. This increased exposure to infections of the digestive tract. Moreover, wherever farmers resorted to irrigation, wading in shallow water exposed them to a debilitating infection called schistosomiasis (or bilharzia), which they shared with snails. And whenever cultivators came to depend on a single crop for nearly all their food, dietary deficiencies were liable to set in. A diet of maize, for example, lacks some of the amino acids humans need and provokes a chronic disease called pellagra. Finally, the domestication of animals, though their meat and milk improved farmers' diets, intensified disease transfers back and forth between humans and their flocks and herds. A large array of bacteria and viruses traveled this path.

Yet intensified exposure to such diseases did not halt the increase in farming populations. Instead more people cultivated more ground, producing more food to feed more children. Farming villages therefore multiplied and spread from the regions where they

had initially established themselves, and human beings soon ceased to be rare in the balance of nature, as their foraging ancestors and other top predators, such as lions and tigers, had always been.

All the same, farmers had to labor longer and at more monotonous tasks than foragers did, and they faced famine whenever bad weather or an outbreak of plant disease provoked crop failure. Seizure of stores of food by human raiders was another serious risk that increased wherever grain farmers became dense enough to occupy nearly all suitable farmland. And when raiders became rulers by learning to take only part of the harvest as rent and taxes, farmers faced another drain on their resources and had to work still harder to feed themselves and their new overlords. Life remained short by our standards, so diseases of old age remained exceptional.

Then, beginning about 3500 BCE, rulers and their various hangers-on began to create cities in a few densely inhabited farming regions of Earth, and

disease patterns changed again, manifesting diverse and unstable local equilibria. These may be described as regional agrarian disease regimes; they were succeeded after about 1550 CE by an equally unstable global disease regime within which we still find ourselves. The balance of this article will explore these successive disease environments.

Regional Agrarian Disease Regimes

When large numbers of persons began to cluster close together in cities, the problem of waste disposal multiplied as never before. Exposure to new infections multiplied as well, since long-distance comings and goings by soldiers, merchants, seamen, and caravan personnel often crossed disease boundaries and spread infections far and wide. Moreover, when urban populations exceeded a critical threshold, a new class of herd diseases began to afflict humans for the first time. These diseases existed initially among large populations of wild flocks and herds, or dense populations of burrowing rodents and other small animals. A distinguishing characteristic of these diseases was that when they were not fatal, they provoked antibodies in their animal or human hosts, so survivors became immune from a second infection. This meant that the germ could only persist when it found enough newborns to feed upon for a few weeks before death or recovery created another crisis of survival for the infection in question.

Just how large the total host population had to be to permit a chain of infection to continue indefinitely depended on birth rates and how closely in contact potential hosts might be. To move from host to host, many infections depended on airborne droplets, set adrift by breathing, coughing, and sneezing, and therefore they needed close encounters for successful transmission. In the modern era (from about 1750), for example, measles—a viral disease dependent on droplet propagation—required at least 7,000 susceptible individuals within a community of something like 300,000 persons to keep going. Obviously, infections like measles could only persist in urban settings and among villagers in contact with large urban centers.

Some of these, like smallpox and measles, were highly lethal; others like mumps and influenza were milder. No one knows when or where they made good their transfer from animal herds to human hosts, but it is certain that it took place somewhere in Asia, perhaps at several different times and places. It is equally sure that they could do so only in and around cities, thus becoming distinctive new “civilized” diseases.

Their arrival had paradoxical effects. By killing off urban dwellers, they soon made most cities so unhealthy that they needed a stream of migrants from surrounding villages to sustain their numbers. Yet these same diseases also created a new and very powerful advantage for disease-experienced populations in contact with previously unexposed populations. That was because among peoples who lacked acquired immunities, herd infections spread like wildfire, killing adults as well as children. In the modern era, initial exposure to measles or smallpox commonly killed off something like a third of the entire population in a few weeks, leaving survivors dazed and distraught and quite unable to resist further encroachment by the disease-bearing newcomers. The effect was multiplied when successive civilized diseases followed one another in rapid succession. Smallpox, measles, influenza, and even the common cold could all be, and often were, lethal.

Before that drastic pattern could establish itself generally, different centers of civilization had to survive the arrival of these infections from wherever they first started. Everything about the initial spread of herd diseases within Eurasia and Africa remains unknown, but disease disasters that ravaged the Roman Empire between 165 CE and 180 CE, and a second time between 251 CE and 266 CE, probably register the arrival of smallpox and measles in Mediterranean lands, brought back by soldiers returning from Mesopotamia. Written records also show that China suffered unusually lethal epidemics in 161–162 CE and again in 310–312 CE.

It looks, therefore, as though extended contacts within Eurasia, arising from the establishment of the so-called Silk Roads that connected China with Syria,

This print by Matsukawa Hanzan enlightened viewers about the importance of the smallpox vaccine and the work of Kōan Ogata, a Western-trained doctor who vaccinated three thousand people in 1849 at his clinic in Osaka, Japan.

allowed highly lethal outbreaks to occur at both extremes of Eurasia at nearly the same time, inflicting severe damage both on the Roman and Chinese empires. But surviving records say little or nothing about lands in between, and guesswork is useless. By contrast, we know that the Americas were exempt from these herd diseases until the Spaniards arrived, and the same was true of other isolated populations around the globe. Consequently, in the sixteenth century, when European seamen began to encounter people lacking immunities to these diseases, massive die-offs regularly ensued.

By then the agrarian peoples of Eurasia had another twelve hundred years of disease exchange and exposure behind them. One well-known episode came between 534 CE and 750 CE, when sporadic outbreaks of bubonic plague ravaged Mediterranean coastlands, only to disappear for the next six

centuries. The historian Procopius wrote an exact description of the initial onset of that plague, explaining that it came by ship and originated in central Africa. Other factors were in play; modern studies show that bubonic plague is spread normally by bites of rat fleas, which transfer to humans only after their normal hosts die of the disease. The domestic rats in question were probably native to India, and in 534 CE they were relatively recent arrivals in Mediterranean coastlands.

The infection itself was at home in underground burrows of various species of rodents in central Africa and northern India, where it behaved like a childhood disease among rats and became a lethal epidemic only when it invaded inexperienced populations of domestic rats and, of course, humans. But under those circumstances it was indeed highly lethal.

Procopius says that when the disease first struck in 534 CE, ten thousand persons died daily in Constantinople for forty days. Loss of population and wealth were certainly severe and prevented the Byzantine emperor Justinian (reigned 527–565 CE) from reconquering the richest provinces of the western empire, which he had started to do.

Germanic and northern Europe escaped this bout with plague, probably because rats had not yet established themselves there. But in the so-called Dark Ages other serious epidemics—including smallpox, measles, and influenza—did break out in the north from time to time, and as ships began to travel the northern seas more frequently, all of Europe became more and more tightly tied into the disease pool centered upon the network of Mediterranean cities. Leprosy, tuberculosis, and diphtheria were among the infections that spread more widely during these centuries. But their spread cannot be traced since they did not provoke sudden, massive die-offs as smallpox, measles, and the plague did.

Nothing equally detailed is known about how other centers of civilization in Eurasia and Africa encountered new infections in ancient and medieval times. But two Chinese texts describe an outbreak of bubonic plague along the southern coast in 610 CE, so it looks again as though China's disease history

matched that of Europe quite closely. This is not really surprising, since the ships and caravans that moved back and forth among all the Eurasian civilized lands carried infections with them, and invading armies occasionally exposed thousands of inexperienced soldiers to a new infection all at once.

North and East Africa shared in this homogenizing process, while the African interior, Southeast Asia, and northern Eurasia took more sporadic parts and so lagged somewhat behind. But overall, as disease exposures intensified across the entire Old World, resistance to infections increased, and local populations got used to living with heavier disease burdens. The assortment of prevalent diseases always differed from place to place, since climate set limits to many infections. In general, warmer and wetter conditions favored disease organisms; infections that depended on mosquitoes, fleas, or other insects to move from host to host also fared best under those conditions. Winter frost set limits to the spread of many kinds of parasites, and so did desert heat and dryness. In addition, local customs sometimes minimized disease exposures. In southwestern China, for example, where bubonic plague germs were endemic among burrowing rodents, European doctors in the nineteenth century scoffed at superstitious villagers who fled to higher ground whenever they found dead rats in their houses, yet half a century later, after Europeans had learned how the plague was transmitted, they realized that such behavior was an effective precaution against catching the disease. Some customs, on the other hand, intensified infections. Religious pilgrimage is a prime example, as was ritual foot-washing in Muslim mosques, where the water in the fountains sometimes contained the organisms that cause bilharzia.

Most disease disasters were soon forgotten, which is why so little is knowable about the spread of infections. But the Black Death was an exception. The heavy die-off provoked when bubonic plague returned to Europe in 1346 continued to haunt folk memory and still colors our common speech. About a third of the population of Europe died of the plague between 1346 and 1350, but what kept

the memory of the Black Death alive was the fact that plague continued to break out from time to time in Europe and North Africa down to the present, even after effective antibiotic cures were discovered in the 1940s. We know something about how this came to pass.

First of all, the vast Mongol Empire, extending from China to Russia, permitted rapid, long-range movement throughout Eurasia on a far greater scale than ever before. Plague was only one of several infections that took advantage of this fact to expand their domain. More particularly, a Mongol army invaded the borderland between China and India in 1252, penetrating a region where plague infection was chronic, and seems to have carried the infection back to its homeland in the steppes. At any rate, *Pasteurella pestis* (*Yersinia pestis*), as the bacterium that causes plague is called, somehow found a new home and spread among burrowing rodents of the northern grasslands, where it was discovered by Russian scientists only in the 1890s. This was the reservoir from which the plague of 1346 broke upon Europe and the Muslim world.

Ships spread it swiftly from Feodosiya (or Kaffa) in the Crimea, where it first broke out, to other Mediterranean and north European ports. Then the infection moved inland. Wherever the plague arrived, death came quickly and unpredictably to young and old. More than half of those infected died. In Muslim lands, the disease took a similar toll; China, too, lost about half its population from a combination of plague and warfare by the time the Mongol Empire collapsed and the Ming dynasty took power in 1368.

Plague continued to visit all these lands at irregular intervals thereafter. The population in Europe continued to decline until about 1480, when the accumulated resistances among survivors at last permitted population growth to resume. It accelerated once the plague disappeared from England and northern Europe after a final visit to London in 1665, partly because efforts at quarantining ships coming from plague-infected ports reduced exposure and partly because slate roofs, introduced as protection against fire, created greater

Indoor plumbing and underground sewage systems advanced public health by helping to control the spread of disease in dense, urban centers.

distance between humans and hungry rat fleas than when rats nested overhead in the thatch. In eastern Europe and Asia, plague continued to break out until the twentieth century, but little by little local adaptations reduced its impact everywhere.

Overall, the most enduring change came to the steppes—the Mongol homelands—where nomadic herdsman found themselves permanently exposed to a very lethal infection. Losses were so heavy that nomads even withdrew from the fertile grasslands of the Ukraine, leaving them vacant for agricultural pioneers to encroach upon, beginning about 1550. This reversed a human tide that had favored nomad expansion ever since the first millennium BCE, carrying first Indo-European and then Turkish languages across Europe and much of Asia.

Other changes in disease patterns accompanied or soon followed the sudden expansion of bubonic plague. The most conspicuous was the retreat of leprosy, emptying thousands of leprosaria that Europeans had built to isolate lepers in accordance with biblical injunctions. Many lepers died of plague during the first onset; but something else must have been at work to overcome the various skin infections that medieval Europeans lumped together and called leprosy. One possibility is Europe's reduced population had a proportionally larger supply of wool with which to clothe themselves, and by wearing long, warm nightclothes and thereby reducing skin-to-skin contact between people, they may have cut

down on the transmission of skin diseases. No one knows for sure.

Ironically, another skin disease, yaws, caused by a bacterium indistinguishable from the one that causes syphilis, may also have been nearly banished from European populations. The epidemic of syphilis that broke out after 1494 may have been the result of the bacterium finding a new path of propagation via the mucous membranes of the sex organs. Again, no one can be sure.

Yet all the mingling and transformations of diseases across Eurasia and Africa before 1500 never erased local differences. Above all, large parts of the Earth remained unaffected by the rising tide of infection among Old World peoples, and they found themselves correspondingly vulnerable when crossing the oceans became routine and a new *global* disease regime began to emerge.

Global Disease Regimes

The first and most overwhelming effect of oceanic navigation was to spread a large array of lethal infections among inexperienced human populations. This process continues in remote Amazon jungles and Arctic shores even today, but by now almost every human population has been at least partially exposed, and the initial shattering effect is past. But when it was new, whole peoples disappeared, and vast landscapes in the Americas and Australia were severely depopulated. Immigrants from Europe and Africa—and subsequently also from Asia—were therefore able to supplant the older inhabitants, creating the mixture of peoples we know today.

Native Americans were the largest population exposed to destruction by the new disease regime. The native population of Hispaniola, where Columbus set up his headquarters, disappeared entirely within a few decades, and within the first fifty years of their exposure to new infections, the much larger populations of Mexico and Peru diminished to about a tenth of what they had been in 1500. Millions died of smallpox and innumerable other infections until

immunities accumulating in survivors' bloodstreams checked the die-off. In Mexico and Peru the worst was over by 1650. Gradually population growth began again, though in more isolated parts of the Americas local die-offs continued. Warfare and less organized forms of human violence played a part in destroying Native Americans, but Afro-Eurasian diseases always had the principal role.

Caribbean islands and tropical coastlands of the Americas also proved hospitable to malaria and yellow fever from Africa once the species of mosquito that carried them came across the Atlantic on board slave ships. No exact time horizon for the arrival of malaria in the New World can be discerned, but in 1648 a lethal epidemic of yellow fever in Havana announced the arrival of that disease unambiguously. When it subsequently became endemic, survivors acquired a very potent protection against invading armies, since soldiers from Europe regularly fell ill and died of it within about six weeks of their arrival. This allowed the Spanish to overcome British efforts to conquer the sugar islands in the eighteenth century, doomed Napoleon's attempt to reconquer Haiti in 1801, and persuaded him to sell the Louisiana territory to Thomas Jefferson in 1803. Quite a political career for a virus from tropical Africa!

Elsewhere, inhabitants of Australia, New Zealand, and other isolated communities experienced approximately the same fate as Native Americans did when disease-experienced Europeans arrived among them. Always the newcomers also brought a rich array of other organisms with them: crops and weeds, together with domesticated animals and pests like lice, rats, and mice. The Earth is still reverberating from the ecological upheavals initiated when humans and innumerable other organisms began to cross the oceans, making the biosphere into a single interacting whole as never before.

Disease exchanges ran almost entirely one way, spreading from Afro-Eurasia to other lands. Reverse transmissions are hard to find, though some experts believe that syphilis came to Europe from the Americas. Europeans discovered that disease when it broke

out in a French army besieging Naples in 1494, so its connection with Columbus's return in 1493 is indeed possible. But there is no clear evidence of the prior existence of syphilis in the New World, so no one can be sure.

Another disease, typhus, also invaded Europe in 1490; but it came with soldiers from Cyprus and may not have been new, but only newly recognized by doctors of the day. More recently, other infections have also invaded disease-experienced populations of the Earth. AIDS is the most serious and widespread, and it may have been transferred recently from monkeys somewhere in the African interior, or perhaps, like typhus, AIDS is much older and remained unrecognized until increasing sexual promiscuity turned it into an epidemic.

Three other new disease exposures affecting industrialized populations in modern times are also worth mentioning. Tuberculosis (TB), a very ancient infection, gained fresh impetus after about 1780 when new factories, powered by coal and steam, began to crowd people together in industrial towns under unsanitary conditions. Its ravages crested in Europe about 1850, shortly before a German professor, Robert Koch, discovered the bacillus that caused it in 1882, thereby inaugurating a new age for preventive medicine. Yet despite modern medical skills, TB remains the most widespread and persistent human infection worldwide, sustained by the extraordinary growth of cities that had carried more than half of humankind into crowded urban settings by 1950 or so.

Cholera, too, was an ancient disease at home in India, where it flourished among Hindu pilgrims who came to bathe in the Ganges. The cholera bacillus can survive independently in freshwater for considerable periods of time, but it multiplies very rapidly in the human alimentary tract and causes diarrhea, vomiting, fever, and often death within a few hours of its onset. Bodily shrinkage from dehydration and skin discolored by bursting capillaries make the symptoms of cholera especially horrible. So when the disease broke through long-standing boundaries in 1819, spreading to Southeast Asia, China, Japan, East

Africa, and western Asia, it aroused intense fear and panic even though mortality rates remained rather modest—a mere 13 percent of the total population of Cairo, for instance. Between 1831 and 1833 a fresh outbreak carried cholera across Russia to the Baltic and thence to England, Ireland, Canada, the United States, and Mexico. Even more important, cholera established itself in Mecca in 1831, where it infected Muslim pilgrims. They in turn carried it home with them, periodically spreading cholera all the way from Mindanao to Morocco until 1912. Then cholera disappeared from Mecca, and Muslim pilgrims ceased to spread it far and wide; but it lived on in India, where Hindu pilgrims continued to be its principal carriers.

European and American responses to this dread infection were strenuous indeed. Reformers in England set out to reengineer the water supply and sewer systems of London and other cities to assure germ-free drinking water. It took years to build new water systems, but as they spread from city to city, many other sorts of infections diminished sharply. Helped by vaccination against smallpox, dating back to the eighteenth century, cities became far more healthful than before. This sanitary effort involved new laws and medical boards of health with mandatory power to enforce preventive measures. It was the first great medical breakthrough of modern times. Bit by bit, vaccination and sanitation spread around much of the globe, changing human experience of infectious disease so fundamentally that we have difficulty imagining times when infant death was a matter of course and adults died of infections more often than from degenerative diseases of old age.

Yet some diseases were little affected by these preventive measures. The viruses that cause influenza, for example, vary from year to year, and regularly find receptive human hosts whose immunities from previous years are ineffective against the new variants. In 1918–1919 a new strain of the virus proved particularly lethal, killing about 20 million persons as it spread around the world, which made it far more

deadly than World War I. Yet, as so often before, survivors soon almost forgot about their encounter with such a lethal epidemic.

That was partly because a second medical breakthrough, comparable to the sanitary successes of the nineteenth century, came after World War II. Suddenly, use of DDT to poison mosquito larvae almost eliminated malaria from many regions of the Earth, while penicillin and other antibiotics became generally available to kill other infections. All at once, instant cures for ancient diseases became a matter of course. On the prevention side, the World Health Organization carried out a successful campaign that eliminated (with the exception of laboratory specimens) smallpox in 1976. Yet these triumphs did not last very long. While effective against mosquitoes, DDT also poisoned so many forms of life that its use was soon abandoned. More generally, infectious agents began to develop resistances to the new antibiotics. As a result, malaria reclaimed some of its old importance, and other ancient infections did likewise.

Then when AIDS was recognized in 1981 and successfully resisted chemical cures, doctors, once so confident of victory over infections, had to admit that their new skills had unexpected limitations. Infections were coming back, and diseases of old age were increasing. All too obviously, and despite all the recent medical marvels, human bodies remain subject to infection and degenerate with age.

Diseases change, and have always done so. Human behavior changes too, affecting how diseases afflict us. Since 1750 or thereabouts, medical knowledge and practice drastically altered the global disease regime and lengthened human life for billions of persons. But all our skills do not change the fact that we remain part of the web of life on Earth, eating and being eaten, everywhere and always.

Diseases—Plant

The relationship between humans and the diseases that afflict plants is intertwined throughout history. Humans were often the ones who unintentionally introduced or spread certain types of disease among plants, which resulted in food shortages and famine. Thus the study of plant diseases remains crucial; whatever threatens crops threatens the health and survival of humans.

Preliterate peoples as well as some literate peoples believed that spirits cause disease. Greek physicians dismissed this notion and instead insisted that disease had physical rather than supernatural causes. In the fifth century BCE, the Greek physician Hippocrates taught that an imbalance of fluids causes disease in humans, a claim that left the cause of disease in plants both ignored and unexplained. In the nineteenth century, the German botanist Anton de Bary, the German bacteriologist Robert Koch, and the French chemist Louis Pasteur swept aside the ideas of Hippocrates. De Bary, working with the potato, and Pasteur and Koch, working with cattle, demonstrated that pathogens (parasitic microbes) cause disease. The germ theory of disease is the foundation of modern medicine.

The focus on human diseases should not deflect attention from plant diseases. Despite a perception to the contrary, plants suffer from more diseases than humans do and for an obvious reason. Plants colonized the land 410 million years ago, whereas modern humans made their appearance only 130,000 years ago. The pathogens that attack plants have had some 400 million more years to evolve new types by mutation than those that attack humans.

Plants diseases often affected history when they provoked famines, but human actions also affected plants from very early times, when our ancestors learned to control fire and began to burn dry vegetation to help their hunting. Subsequently, humans carried seeds to new locations when they began to plant fields of grain and other food, and eventually they carried favored crops all around the world. They also spread plant diseases unintentionally together with weeds, as well as animals and insect pests. Plants and humankind, in effect, interacted so closely that they began to evolve together. Even as nomadic foragers, humans depended on plants for sustenance. The rise of agriculture in western Asia some 10,000 years ago and its spread throughout the world have wedded the destiny of humans to that of crops (domesticated plants). Whatever has threatened crops has threatened the health and survival of humans.

Diseases of the Staple Grasses

Grasses such as wheat, rice, and rye have been the staple crops that have sustained populations over the centuries; thus the diseases associated with them have great impact on humans, potentially affecting not only food supplies but their health as well.

Wheat Rust

Wheat rust is one of the oldest plant diseases. Some scholars believe that a passage in Genesis records an outbreak of rust in the Levant that caused famine so severe it forced the Hebrews to migrate to Egypt, the granary of the ancient Mediterranean world. If these

scholars are right, this text is the earliest written account of a plant disease.

Only in the fourth century BCE did Theophrastus, a Greek botanist and pupil of Aristotle, coin the term *rust* for this disease because of its reddish hue on the leaves and stem of wheat plants. Theophrastus wrote that wheat planted in valleys and other low ground suffered from rust more often and more acutely than wheat planted on high ground, though he could not explain this fact.

That insight came to the Romans. As early as 700 BCE, they identified the reddish hue on wheat plants as the mark of rust. At that time they began to worship Robigus; historians identify Robigus as the god of rust, a fair statement so long as one remembers the Greek rather than Roman origin of the term *rust*. The idea that a god unleashed rust on the Romans underscores their belief that rust had a supernatural cause. Trade with the Greek city-states led the Romans to abandon a supernatural explanation of plant diseases. In the first century BCE, the naturalist Pliny the Elder made

the crucial link between moisture and the onset and spread of rust, writing that rust afflicted wheat grown in areas where fog and dew were common in morning and evening. Pliny's insight into the role of water in spreading rust was prescient because rust, like all fungal diseases, spreads in wet environments. The rust fungus needs water to produce the millions of spores that are the next generation of fungi. Two centuries later, the agricultural writer Columella warned farmers against staking their livelihood on wheat. The only protection against rust was to grow a diversity of crops. Columella recommended cultivation of chickpeas and lentils because of their immunity to rust.

Columella had reason to worry: the first three centuries of the Common Era were unusually wet in the lands along the Mediterranean Sea, bringing rust to wheat fields throughout the Roman Empire.

In the seventh and eighth centuries, Arabs brought the barberry bush with them as they swept across North Africa and into Spain. Neither Arabs nor Europeans understood that the bush harbors rust fungi

Close-up of wheat rust, one of the oldest plant diseases.

Photo by James Kolmer for the United States Department of Agriculture, Agricultural Research Service.

because the fungi inhabit the bush without harming it, much as the pathogens that cause malaria and yellow fever live in the gut of the female mosquito without harming her. A barberry bush that harbors rust fungi has no symptoms of disease. Only in the seventeenth century did Europeans begin to suspect the bush to be a Trojan horse. In 1660 France enacted the first law to eradicate the bush. Other European nations passed similar laws, as did the American colonies in the eighteenth century.

These measures were not enough to stop the spread of rust. Plant breeders in the nineteenth century began to search for rust-resistant wheat to cross with high-yielding but susceptible varieties; this effort accelerated during that century as England, France, the German states, and the United States poured money into agricultural science. Around 1900 agronomists at the U.S. Department of Agriculture identified an Italian durum wheat suitable for pasta and a Russian emmer wheat suitable for bread. These were the first of innumerable resistant wheat varieties that give humans the best, if incomplete, protection against failure of the wheat crop from rust.

Rice Stunt Disease

Chinese records first mention the cultivation of rice four thousand years ago, though its cultivation began earlier in southeastern Asia. By 500 BCE, farmers grew rice in China, the Korean peninsula, and the swath of land between modern Vietnam and India. By the first century CE, farmers were growing rice in Japan, Indonesia, and the Philippines. The people of these regions were nearly as dependent on rice as the Irish would be on potato in the nineteenth century. True, farmers also grew soybeans throughout Korea and China, and wheat grown along the Indus River reached the people of central and southern India by trade, but soybeans and wheat were minor supplements to a diet of rice.

Roughly forty diseases afflict rice, making difficult the task of sorting among them difficult, as well as among climatic factors, to explain the 1,800 famines that Chinese documents have recorded since 100 BCE and the seventy in India since 33 CE. Because rice

needs more water than any other grain to thrive, Chinese and Indian texts often attributed crop failures to inadequate or impure water.

In the sixth century CE, a Japanese text mentions stunted (short or dwarf) rice plants that bore little or no rice. The condition baffled farmers for 1,200 years. In 1733, 12,000 Japanese died of famine when stunt destroyed their rice crop, yet no one was any closer to understanding what stunted rice plants. Unlike Europe, Asia never developed science in its modern form but only gradually assimilated it from Europeans during the eighteenth and nineteenth centuries. The people of Japan and continental Asia did, however, have a tradition of careful observation. This tradition led one Japanese farmer in 1874 to study the feeding habits of leafhoppers on rice plants. He doubted that insect bites alone could arrest plant growth and instead proposed that leafhoppers carried a pathogen that they transmitted to rice plants by bite. The pathogen, not leafhoppers, stunted rice plants.

The idea was as novel as it was correct. Leafhoppers carry within their gut Rice Dwarf Virus just as, one may recall, various species of mosquitoes carry the pathogens for malaria and yellow fever. Rice Dwarf Virus remains virulent throughout a leafhopper's life, and female leafhoppers pass the virus to their offspring, multiplying it with each generation. When the leafhopper population is large, as it must have been in Japan in 1733, the virus becomes widespread enough to cause failure of the rice crop even though the leafhopper is an inefficient flier.

The discovery of insect transmission of a pathogen opened a new field in the study of plant diseases by uniting entomology, the study of insects, with plant pathology. Scientists came quickly to understand that control of insect populations is essential if one hopes to minimize crop damage from an insect-borne pathogen. It was no longer enough for the plant pathologist to understand diseases. He now had to understand the feeding and mating habits of insects and their distribution in areas of disease. The need to combat insects accelerated the study and development of insecticides as a branch of applied chemistry in the twentieth century. The study of insect-borne viruses and the development

and use of insecticides would later be crucial in fighting corn diseases in the United States.

Rye Ergotism

The importance of wheat and rice to the sustenance of Europeans and Asians has deflected attention from rye and its diseases. The Germanic tribes that settled the lands that are today France and Germany began growing rye in the second century CE. Wheat always commanded a higher price than rye, making rye bread the staple of the poor until the even cheaper potato spread through Europe between the sixteenth and nineteenth centuries.

The diseases of rye thus afflicted the poor rather than the rich. Particularly serious was ergotism, a fungal disease that fills rye grains with a toxin that in sufficient quantities causes convulsions and death in humans. Unlike most plant diseases, ergot of rye threatens humans by poisoning them rather than by causing famine. The agony of death from ergot toxicity led medieval Europeans to attribute the disease to God's wrath, hence the name "Holy Fire." Medieval chronicles cite the first outbreak of Holy Fire in the eighth century. In 857 CE, thousands died in the Rhine Valley, with smaller outbreaks throughout France and Germany.

One may recall that fungi spread in wet environments. Evidence from dendrology and medieval chronicles suggests that after 1000 CE, Europe's climate turned wet and cool, hastening the spread and severity of ergotism in northern and western Europe. An outbreak in 1039 was the first in a series of virulent outbreaks between the eleventh and eighteenth centuries. Ergotism, along with famine in the early fourteenth century, may explain the high mortality of the Black Death.

Diseases of the Staple Crops Indigenous to the Americas

Like grasses in Europe and Asia, dependence on certain crops can be dangerous—culturally and economically—if they become susceptible to disease.

A drawing from the *Illustrated London News*, 22 December 1849, shows a family affected by famine. The potato blight in the mid-1840s decimated the staple crop of the Irish; one million starved and 1.5 million fled Ireland in the next five years.

Potatoes and corn are two staple crops that have been catastrophically affected.

Late Blight of Potato

The fungus that causes late blight of potato is at the center of a tragedy, the Irish Potato Famine. The tragedy has its roots not in Europe but in the Andes Mountains, where the natives of Peru domesticated the potato. The Spanish conquered Peru in the sixteenth century. In search of gold, they found a more valuable commodity, the potato. From Peru the potato reached Spain by ship around 1570, reaching Ireland before 1650.

By 1800 the Irish, squeezed by their lack of land and high rents, had no choice but to embrace the potato for sustenance because it yielded more food per unit of land than any grain. Reliance on a single

crop is always risky, as Columella had emphasized in the first century. The potato posed risks far greater than the Irish could have imagined. The Spanish had brought little more than a few handfuls of potatoes with them. These potatoes were of the same stock and thus genetically uniform. Because the potato propagates by shoots, new potatoes, barring mutation, are genetic equivalents of the parent potato. With all potatoes near carbon copies of one another, any disease that threatens one potato threatens all.

With the potato vulnerable, catastrophe struck in 1845. Six weeks of rain hastened the spread of the blight fungus across Ireland. The plants died and potatoes rotted in the ground. Blight struck again in 1846. Their staple gone, one million starved and 1.5 million fled Ireland in the next five years.

The tragedy galvanized scientists throughout Europe into action. In 1861 Anton de Bary isolated the culprit, a fungus he named *Phytophthora infestans*, and by spreading it on healthy potato plants demonstrated that it caused blight. The Potato Famine had spurred de Bary's discovery, which marked the beginning of plant pathology as a science.

Corn Diseases

As with potato diseases, scientists know little about corn diseases during the pre-Columbian period. What is clear, however, is that corn, unlike potato, is a cross-pollinating plant that produces plants with genetic diversity. Crossbreeding achieves diversity by reshuffling chromosomes in any plant or animal, including humans. This diversity should minimize the occurrence of epidemics, for within a heterogeneous population some individuals, in this case corn plants, should be resistant to disease.

Corn Viruses

Since the 1920s, corn breeders have reduced the genetic diversity by breeding a small number of high-yielding corn plants of roughly uniform genotypes, making corn vulnerable to epidemics. An outbreak of corn stunt disease along the lower Mississippi valley in 1945, reminiscent of the stunt disease that ravaged rice in Asia, presaged corn's vulnerability to an

epidemic. As is true of rice stunt, a virus causes corn stunt disease and is spread by an insect, in this case a species of aphid.

Worse was to follow. A few stunted corn plants in Portsmouth, Ohio, erupted in an epidemic that engulfed the Ohio and Mississippi valleys in 1963 and 1964, costing farmers who had planted on some lands along these rivers their entire corn crop. The culprit was not the corn stunt virus as scientists first thought but two viruses: Maize Dwarf Mosaic Virus (MDMV) and Maize Chlorotic Dwarf Virus (MCDV). The initial confusion among scientists slowed their response, opening the entire Midwest and South to the danger of an epidemic.

The method of virus transmission saved corn growers. A species each of aphid and leafhopper transmits MDMV and MCDV, respectively, by bite. Both feed primarily on Johnsongrass that grows along the Ohio and Mississippi rivers. Both viruses inhabit Johnsongrass, as the ergot fungus inhabits the barberry bush, without signs of disease. But neither insect is a strong flier, and, unlike the leafhopper that carries Rice Dwarf Virus, neither aphid nor leafhopper retains MDMV and MCDV in virulent form more than forty-five minutes, limiting the range of both viruses.

Once scientists had fingered the aphid, leafhopper, and Johnsongrass as culprits, the U.S. Department of Agriculture launched a campaign to kill aphids and leafhoppers by insecticide and Johnsongrass by herbicide in late 1964. The expenditure of chemicals and money ended the threat of these viruses and led scientists to believe they held the upper hand against corn diseases. Success prevented all but a few scientists from questioning the wisdom of growing genetically uniform corn throughout the Midwest and South.

Southern Corn Leaf Blight

Catastrophe struck in 1970 as Southern Corn Leaf Blight, a fungal disease, swept the United States, destroying 710 million bushels of corn, 15 percent of the corn crop that year. From Texas to Georgia and Florida, farmers lost half their corn crop. These losses cost farmers \$1 billion, and the collapse of farm commodity prices cost investors billions more. In a single summer, one corn fungus threatened financial ruin.

Plant pathologists identified a single female parent of corn (a type of corn that produced no pollen and so was male sterile) as susceptible to Southern Corn Leaf Blight. By dropping it from the corn pedigree, agronomists bred new varieties of corn resistant to South Corn Leaf Blight, but corn remains as genetically uniform today as it was in 1970.

Future Prospects

The imperative to minimize crop losses from diseases will only intensify in the future as the human population grows exponentially. At their origin 130,000 years ago, modern humans cannot have numbered more than a few thousand. Only around 1800 did the human population number 1 billion. The population doubled by 1940 and again by 1975. Today, more than 6 billion humans crowd the earth, and demographers fear our numbers may swell to upwards of 9 billion by 2045.

To avert famine on an unprecedented scale, farmers must triple food production by then. To fall even 2 percent short of the goal, demographers believe, will condemn some 270 million people to starvation. Only with the highest yielding varieties of potatoes, corn, soybeans, wheat, and rice—the sustenance of humanity—can humans hope to avert widespread starvation. But only a small number of varieties of any crop can yield enough food for a hungry world. The future will only exacerbate the problem of genetic homogeneity. Crops may become more rather than less vulnerable to epidemics.

Domestication, Plant and Animal

One of the greatest survival techniques of the human population was the domestication of their environment. Domestication, based on human preference, changed the natural behavior and characteristics of the plants and animals they chose to cultivate. The earliest examples of plant and animal domestication date back hundreds of thousands of years, but the environmental effects of those lifestyle changes are still apparent today.

Domestication of plants and animals is the most fundamental subsistence change in human history. For 100,000 years or more, humans subsisted only by foraging and hunting. Then, near the end of the Pleistocene epoch (1.9 million–10,000 BCE), people in a few regions of Earth independently began to control and breed the species they had hitherto only collected. Between 12,000 and 5000 BCE food producing began to replace food collecting. In the process humanity gained unprecedented control of the natural world, and human populations grew geometrically. But adaptive success was purchased at the price of ecological disruption, new infectious diseases, and accelerated environmental destruction.

The theory that domestication took place in a single limited area and then spread by diffusion throughout the rest of the world has been discredited. It now appears that plant and animal domestication occurred independently and repeatedly within six or more primary “hearths” in southwestern Asia, sub-Saharan Africa, peninsular southeastern Asia, Eastern Asia, Mesoamerica, and Andean South America. Later, more limited domestication took place in secondary

“hearths” such as southeastern North America and southern Asia.

Locating these hearths is easier than determining why such profound adaptive changes occurred within them. The ethnographic (relating to the study of human cultures) record indicates that, as a rule, foraging peoples do not farm unless new circumstances make foraging difficult or impossible. Therefore, the transformations of food-collecting systems into food-producing ones at the end of the Pleistocene epoch may have been caused by worldwide climate changes, mammalian extinctions, sea-level rise, and apparent human population increases that also occurred around that time. Archeologist Mark Cohen (1977) argues that, although prehistoric foraging populations grew throughout the Pleistocene epoch, the pressure of population on food resources became critical only when climatic and environmental changes at the epoch’s close undercut existing foraging economies. As environments became increasingly less productive, population pressure forced foragers to intensify and expand their subsistence activities. According to economic historian Frederic Pryor (1983), such intensification might have included taming animals and tending plants in order to (1) reduce the risks arising from overreliance on increasingly unreliable wild foodstuffs, (2) supplement wild foodstuffs available primarily in one season with cultivated foodstuffs available in another, (3) utilize the labor of marginal members of societies who were unable to participate fully in the primary food-collection activities, or (4) simply add variety to the diet.

Where taming and tending were practiced over the long term on suitably malleable species, it likely

*Corn planted us; tamed cattle made us tame. / Thence hut and citadel
and kingdom came.* • Richard Wilbur (b. 1921)

resulted in domestication. Not all scholars, however, accept the “food crisis theory” and instead favor other causes, including human population growth, differentiation and specialization within human adaptive systems, or creative human manipulation of the environment.

Plant Domestication

Whatever their reasons for doing it, after people began to systematically replant the seeds they gathered, they interposed *human* selection between the organisms and the *natural* selective forces of the environment.

A common procedure at harvest time is for the cultivator to go through his field and carefully select heads to be saved as stock seed for the next planting. The rest of the field is harvested for consumption. In this situation, selection is total. The components of the population that contribute to the next generation are those chosen by the cultivator. The rest are eliminated from the gene pool. (Harlan, De Wet, and Stemler 1976, 8)

As a result, some genetic mutations that would ordinarily be eliminated in the wild come to be favored in the cultivator’s field. In cereal grasses such as wild wheat, barley, oats, or rye, seed-dispersal mechanisms are the first to change under cultivation. Wild grains have excellent means of scattering their ripe seeds because natural selection allows only the genes of plants with efficient dispersal mechanisms to be transmitted to succeeding generations. Although genetic mutations retarding seed dispersal occur in each generation in wild populations, they are fatal to the progeny of the plants that carry them. Yet, the seeds of wild plants with retarded seed-dispersal mechanisms are easier for humans to collect. It is their seeds that are unconsciously selected by collectors. When collectors began to *reseed* their fields, such mutations began to survive. Reseeding may have first been done by collectors seeking to introduce wild cereals into habitats outside their natural range. Whatever the reason, when collectors began saving and planting some of the seeds

they harvested, greater and greater numbers of the dispersal-retarding mutations were concentrated in the grain populations. Generations of unconscious human selection genetically altered the grain and increased its harvestability and, therefore, the productivity per unit of labor invested in its collection.

Harvesters also unconsciously favored uniform rates of seed maturation. Wild cereal seeds do not germinate at the same time but rather tend to sprout throughout the growing season. Some even remain dormant for years. Cultivated cereals are harvested all at once. Individual plants that produce the most seeds at harvest time thus make the greatest contribution to the next generation. In this way, harvesting narrows seed germination ranges and reduces prolonged seed dormancy.

A trend toward larger seeds is also common, although not entirely universal, in cereals under cultivation. The increased size of domesticated seeds is partly due to conscious human selection of the largest seeds for replanting, but larger seeds also result from seedling competition. Seed size is closely related to seedling vigor, and the seedlings that sprout first and grow fastest in the seed bed are the ones most likely to contribute genes to the next generation.

In addition to these unconscious selective behaviors, a variety of others is imposed by the cultivators’ conscious preferences in taste, color, ease of processing, and storage. As a general rule, the part of the plant most used by humans is the part most modified by human selection. Consequently, little resemblance exists between the ears in maize, the tubers in yams, or the pods in peas and the comparable organs in the wild ancestors of these plants. Domesticated plants have been sculpted by human selection. As the process continues through time, plants lose, to a greater or lesser degree, their capacity to survive without direct human intervention in their life cycles.

Domestic wheat, a cereal grass of the genus *Triticum*, has proven to be the most significant cultivated plant in human history. Yet, such minor genetic differences separate wild and domestic wheats that they might readily be included in the same species. This

genetic proximity suggests that the domestication of wheat was both simple and rapid. Recent experiments in the measurement of domestication rates done by archaeologist Gordon Hillman and plant scientist Stuart Davies (1990) indicate that wild einkorn and emmer wheats could have become completely domesticated in twenty to two hundred years. By contrast, the domestication of maize or corn appears to have taken upward of two thousand years.

Maize (*Zea mays* spp.) evolved from the wild grass-like perennial *teosinte* in Mesoamerica and northern South America. The earliest evidence of what is probably maize comes from a pollen profile dating to 5100 BCE. The earliest definite archeological maize remains were recovered at Guilá Naquitz, a dry rock shelter in Oaxaca, Mexico. These tiny cobs date to about 4200 BCE and came from plants in an early stage of domestication. Maize does not appear to have been fully domesticated until about 3000 BCE. From that time forward, it was widely cultivated in North and South America. The slow pace of maize domestication is striking considering that squash (*Cucurbita* spp.), another New World cultigen (an organism of a variety or species for which a wild ancestor is unknown), was first cultivated between 8000 and 6000 BCE.

Although maize produces more foodstuffs per unit of cultivated land than any of the other Native American crops, it has nutritional disadvantages. Most notably, certain of its amino acids are difficult for humans to process. Native Americans learned to enhance the nutritional quality of maize by boiling dried kernels in a lime solution before grinding them into flour. Beans (*Phaseolus* spp.) supply many of the nutrients missing in maize, and Native Americans also learned to grow and consume the two crops together.

Although a vast array of vegetables is grown in eastern Asia, dry and wet rice (*Oryza* spp.) are the focus of cultivation there. In the world at large, only wheat exceeds rice in dietary importance. Although it has been suggested that rice domestication began about 15,000 BCE, the earliest archeological evidence of domesticated rice, recovered at sites from northern Thailand and the well-watered, tropical regions of southern China, is no earlier than about 5500 BCE.

Rice cultivation spread to—or emerged independently in—northern China shortly after this time.

Millet is the common name for a number of drought-resistant cereal grasses widely used as human food, animal forage, and hay. Most species tilled today were apparently domesticated in northern China. As one moves from south to north in China, rainfall levels and mean annual temperatures decline. Not surprisingly, the plants domesticated in northern China contrast markedly with those in southern China. Foxtail (*Setaria italica*), pearl millet (*Pennisetum americanum*), broomcorn millet (*Panicum miliaceum*), and other species were probably domesticated on the upper and middle reaches of the Yellow River. After millet's domestication, various millet races spread throughout semiarid mainland Asia and arrived in Taiwan between 4000 and 2500 BCE.

In tropical and subtropical regions of the world, cultivation traditionally centered on asexually or vegetatively reproduced root crops such as arrowroot (*Maranta* spp.), yams (*Dioscorea* spp.), potatoes (*Solanum tuberosum*), taro (*Colocasia* spp.), cassava or manioc (*Manihot* spp.), and fruit trees such as bananas (*Musa* spp.). Seeds are not necessary for their reproduction. These plants all have the capacity to regenerate tissues and structural parts, either naturally or through human cutting or grafting. By reproducing plants asexually, farmers are able to preserve desired characteristics from generation to generation. Intensive human vegetative husbandry has caused some species to lose their capacity for sexual reproduction altogether. The ease of this manner of horticulture suggests that root crop domestication by vegetative reproduction may have preceded the domestication of cereal grains and other seed crops. Domesticated root crops were present in Panama by 5000 BCE.

Animal Domestication

It is generally assumed that, confronted by humans, wild animals instinctively either fight or flee. But zooarcheologist Charles Reed (1986) contends that most, in fact, are easily tamed. In his view, the major impediment to their domestication was human

hunting. Subsistence systems that minimized hunting were the most likely to have initiated the domestication process; those that specialized in hunting were the least likely to have done so. Recognizing the signs of domestication in skeletal remains from archeological sites is not often easy. Fortunately, in recent years the analysis of DNA has proved a helpful supplement to archeology.

The skeletons of dogs (*Canis familiaris*) dated to about 12,000 BCE and recovered from hunting camps in Palestine constitute the earliest definite archeological evidence of animal domestication of any kind. One can see why dogs were the first to enter the human orbit. Canines are willing scavengers; their wolf ancestors must have skulked around the edges of human camps since time immemorial. Eventually such skulkers would have become semidomesticated. Full domestication—and human recognition of the utility of dogs in the hunt—no doubt came later. But how much later? A recent comparison of wolf and dog DNA sequences suggests the two species diverged more than 100,000 years ago. Few prehistorians are prepared to accept such an early date for the onset of domestication. Genetic analysis of a large sample of contemporary dogs worldwide suggests that the domestic dog is most likely to have originated in eastern Asia fifteen thousand years ago and to have spread from there. Related DNA analysis suggests that New World dogs originated in the Old World and then, in company with peoples crossing the Bering Strait land bridge, entered North America near the end of the Pleistocene epoch.

Ovicapripnes—sheep (*Ovis* spp.) and goats (*Capra* spp.)—were the next animal species to enter the human orbit. Archeological evidence suggests that their domestication probably occurred as early as 9000 BCE in the mountainous regions of eastern Turkey and western Iran. Wild ovicapripnes were “preadapted” for life with humans; easy to tame when young, they can digest a wide range of plants that humans find inedible. More importantly, their alpha (dominant) males neither defend individual territories nor assemble exclusive harems. Ovicapripnes thus can be kept in sociable, mixed-sex herds. Between about 7000 and

6000 BCE domestic goats and sheep became the principal source of meat and hides for the earliest farmers of southwestern Asia. Their dispersal throughout Eurasia and Africa after that time appears to have been rapid.

Domestic pigs are descended from the wild boar (*Sus scrofa*), a species originally found throughout broadleaved, deciduous (leaf-dropping) forests from Eurasia to northern Africa. Although adult boars are dangerous, wild piglets are easily tamed. Archeological evidence suggests that pig domestication began slightly later than ovicapripnes and independently in southwestern and eastern Asia.

The placid domestic cow of modern times, *Bos taurus*, is a descendant of *Bos primigenius*, the Old World wild cow or auroch (plural *aurochsen*). Aurochsen became extinct in the seventeenth century. Their behavior, however, can be inferred from accounts of Spanish longhorn cattle that reverted to the wild in frontier Texas and California. Longhorns were fierce, quick, willing to attack without provocation, and hard to kill. If aurochsen, which often reached 2 meters at the withers, behaved like longhorns, they must have been among the most formidable creatures encountered by prehistoric people. This leaves researchers wondering what possessed human forebears to domesticate them. Perhaps only religious motivation would have induced people to do so. Aurochsen might have been driven into natural enclosures from which individual animals were extracted for sacrifice. Eventually herds thus impounded might have been kept and bred. Whatever the motive for it, cattle domestication began about 7000 BCE in Anatolia, Greece, and parts of southwestern Asia. Significantly, archeological evidence of bull worship at around 6000 BCE has come to light at early sites such as Çatal Hüyük in Turkey and elsewhere in the eastern Mediterranean. Once domesticated, cattle spread quickly. *Bos taurus* bones dating to about 4500 BCE have been recovered in northern Africa at Capeletti. Cattle herders expanded south into the Sahara desert during a moist period there between about 5500 and 2500 BCE. Rock paintings at Tassili in the central Sahara depict long-horned, humpless

cattle of apparent *Bos taurus* stock. The desiccating Sahara pushed herders farther south. Domesticated cattle, presumably taurines, were present in eastern Africa by about 3000 BCE. The expansion of herders throughout sub-Saharan Africa was well underway after that date. However, recent DNA evidence suggests the possibility that native African cattle were already domesticated in sub-Saharan Africa prior to the arrival of taurine stock.

Southern Asia was a third center of independent cattle domestication. It was a primary hearth for the domestication of the water buffalo (*Bubalus bubalis*) and humped Zebu cattle (*Bos indicus*). Zebu cattle from the Indian subcontinent appeared in eastern Africa sometime after about 1000 BCE. Infusion of such stock must have improved African herds. Zebu cattle generally need less water and forage than taurines and gain back weight more quickly after droughts. Crossing Zebu with local breeds may also have produced more disease-resistant cattle capable of greater milk yields.

Cattle were the earliest pack transport and traction animals, but, following their domestication, horses (*Equus caballus*), donkeys (*Equus asinus*), and camels (*Camelus* spp.) performed both tasks more efficiently. Although all three were likely domesticated for their meat, hides, and milk, the subsequent mastery of riding of these species revolutionized human trade, transportation, and warfare. The donkey, apparently the first of the horse family (Equidae) to be domesticated, appears in the archeological record of Mesopotamia about 4000 BCE. DNA analyses of modern horses suggest that their domestication occurred in many centers in Eurasia. Archeological remains indicate that horses were certainly being raised on the steppes north of the Black Sea by 3000 BCE. Archeological evidence of domesticated camels is poor, but these animals are probably present in southwestern Asia by 3000 BCE.

The late Pleistocene extinctions that swept through the New World eliminated wild species, such as horses and giant camels, which might otherwise have been domesticated. The key grazing animal species to survive—pronghorn antelope (*Antilocapra americana*) and American buffalo (*Bison bison*)—make

poor domesticants. Although social like ovicaprines, pronghorns differ from them in the amount of body contact they will tolerate. They are not “contact animals” but rather maintain distance between each other. Adult male pronghorns have a well-developed sense of territory. They strive mightily to keep females inside their territory and other males outside of it. These traits render domesticating pronghorns difficult and herding them nearly impossible. Bison also exhibit behavioral traits that make handling difficult even for contemporary herders. Not surprisingly, both species remained wild into modern times. Thus, the number of potentially domesticable animals in the Americas was limited. Compared to the extraordinary array of New World domesticated plants, the array of domesticated animals was paltry indeed. It included only dogs, Muscovy ducks (*Cairina moschata*), turkeys (*Mele agris gallopavo*), Guinea pigs (*Cavia porcellus*), and various forms of New World camelids (*Lama* spp.) such as the llama, vicuña, guanaco, and alpaca. This dearth of domesticated animals had fatal consequences for New World peoples—a fact dramatically illustrated in Mexico and Peru by the rapid military triumphs of mounted sixteenth-century Spanish conquistadores. But the low number of pre-Columbian domesticated animals had a positive side: it reduced Native American exposure to deadly diseases passed from animals to humans.

Silent Domestication

Domestication of plants and animals in the visible world was accompanied by domestication of organisms in the invisible microbial world. Many of these microbes were benign or useful. Yeast, for example, makes fermentation possible. Systematic fermentation is impractical, even impossible, in the absence of sealable pottery jars. Yeast domestication must therefore have been an unintended consequence of ceramic manufacture. Fermentation processes dependent upon yeast include pickling, cheese making, bread making, culturing, and producing vinegars, sauces (especially fish sauces), and lactic acid fermentations of various vegetables such as sauerkraut. Fermentation

can preserve food, remove toxic components, utilize food wastes, and supply essential secondary food constituents. Fermented sauces and relishes improve flavor or disguise its defects.

The fermentation of wine and beer must not be forgotten. Early wine was made from honey, palm sap, dates, figs, raisins, apples, pomegranates, and numerous other fruits. Beer, fermented chiefly from wheat and barley, made an important contribution to the nutrition of the grain farmers who consumed it. Cereal porridge lacks vitamins of the B-complex. Happily, most beers are rich in B-complex vitamins. But human adaptation proceeds on the mental plane as well as the material. Beer and wine help here, too; English poet A. E. Housman wrote, "And malt does more than Milton can / To justify God's ways to man" (1988).

The achievement of early farmers in harnessing the microbes of fermentation is impressive indeed. Their practical understanding of the ferments is especially remarkable because it was gained by trial and error in a prescientific context. In addition to yeasts and bacteria, early farmers domesticated numerous lower plants such as mushrooms, fungi, and algae. Cultivation of yeasts, bacteria, and lower plants offers three advantages: short production cycles, modest space needs, and low water requirements. Further, the relative simplicity of their husbandry requirements allows the character of the final product to be precisely controlled.

Unfortunately, silent domestication had a more sinister aspect. By living intimately with their domestic animals, humans altered the transmission patterns of existing animal pathogens (agents of disease) and stimulated the evolution of new ones. Humans came to share the diseases of the creatures they exploited. Old World examples include measles, tuberculosis, and smallpox (derived from cattle) and influenza and pertussis (from pigs and perhaps ducks and dogs). There are many others, some of which spill back from domestic animals to wildlife that come in contact with them.

By making life more sedentary, early farming brought people into sustained contact with fecal

wastes, both human and animal. Absent a clear recognition of the relationship between feces and disease, farmers were not overly careful about the disposal of human and animal waste and seemed to have made little systematic effort at preventing their food and water from becoming contaminated by sewage. Such contamination provides ideal environments for the transmission of diseases such as diarrhea (particularly dangerous for small children), typhoid, and cholera. Intestinal parasites such as worms and protozoa also spread readily in this environment.

This brings the discussion once more to beer. To a certain extent, these diseases can be avoided by not drinking the water and making do with beer and wine instead. Alcoholic ferments were thus an important cultural adaptation to the new conditions of disease and health created by the silent domestication processes active in early farming life.

Weeds

Microbes were not the only set of unintended domesticants. Another set, weeds, was found on the margins of the cultivators' fields. *Weed* is a folk, not a scientific, term. It refers to plants that rapidly colonize soils disturbed and stripped of vegetation by fires, landslides, windstorms, floods, and so forth. Before the advent of agriculture, there were relatively few of these plants. However, land clearance for agriculture dramatically expanded the habitat of such pioneers and, eventually, turned them into unintended cultivars (organisms originating and persisting under cultivation) dependent upon human environmental disturbance and subject to human manipulation. In this way, new varieties of weeds were produced as the by-products of cultivation. These new varieties emerged as hybrids when wild and domesticated races of cereals and other plants were grown together in the same fields. Some weed species were ultimately domesticated. Both rye and oats were European weeds that entered the repertoire of Old World domesticates when farmer-colonists began farming the interior of that continent. But most weeds remain semidomesticated pests and bedevil cultivators to this day.

The spread of farming carried these weedy pests into new territories. The best evidence for the arrival of agricultural peoples in northern Europe is the appearance of such characteristic Mediterranean weeds as ribwort plantain (*Plantago lanceolata*), stinging nettle (*Urtica dioica*), and various kinds of sorrels (*Rumex* spp.). The later spread of European agriculture into the New World, Australia, and the islands of the Pacific introduced these Old World weeds with devastating effect.

Human-Caused Environmental Destruction

By late prehistoric times few of the Earth's terrestrial ecosystems had not felt the impacts of humankind. Not all impacts were of the same magnitude, however. Hunting-and-gathering peoples had a comparatively modest effect, whereas farmers radically changed natural conditions wherever they went. By clearing, burning, and killing wild predators and later by plowing and irrigating, they overrode local constraints and created new, relatively homogeneous environments. Agriculture represents an ecological simplification of human subsistence. It narrows human dependence to a limited range of plant and animal species largely controlled by the farmers themselves. When tended by humans, this array of domesticated species can adapt to a wide range of environments. The adaptability of their animals and plants, combined with their efforts at transforming the environment, meant that agriculturalists were less obliged to learn the ins and outs of their new ecologies and cared little for preserving wild food resources. By altering their environment and increasing the size of the human population supported by it, farmers made it difficult for hunting-and-gathering peoples to subsist. Along with agricultural peoples and their animals came deadly zoonoses (diseases communicable from animals to humans). As prehistory drew to a close, continued population growth generated by agriculture stimulated ever-more-intensive forms of cultivation and husbandry such as dairying, wool raising, irrigation agriculture, and its twin, fully nomadic pastoralism.

Inexorably, growth and intensification led to the rise of cities, states, and civilization. From then on, there was no going back.

Drugs, Psychoactive

Trade in drugs began to flourish in the late 1400s, when European coastal cities played a major role in determining whether a drug would become a global commodity. Drugs were ideal money makers, some with addictive effects that ensured constant demand. Taxes placed on such drugs often funded a nation's politics, and revulsion to this eventually led to nineteenth-century prohibitions and regulations.

Psychoactive drugs became global commodities with the expansion of oceanic trade from the late fifteenth century. In many ways the diffusion of drugs resembled that of germs: that which had been confined to one region, continent, or hemisphere spread around the world. The principal difference was that drug production and commerce were deliberate and profit motivated, while the introduction of germs was not. Only from the late nineteenth century onward did political elites reevaluate the lucrative international trade in drugs and begin selectively imposing restrictions.

The most important drug commodities produced and traded in both hemispheres were alcoholic and caffeinated beverages, tobacco, opiates, cannabis, and various coca products. Psychoactive exchanges occurred in both directions, from west to east and east to west. Tobacco, coca, and cacao originated in the New World and spread to the Old. Liquor, wine, opium, and cannabis originated in the Old World and spread to the New. Sugar cane, another important transplant from the Old World, was used to make rum. Sugar also sweetened bitter-tasting psychoactive products, among them chewing tobacco, coffee, tea, chocolate, and even opium.

Not all local or regional drugs became global products. For reasons that ranged from spoilage problems to cultural prejudice against their effects, use of khat, kava, betel, peyote, mescal beans, and many other substances remained confined to one hemisphere or the other. For a drug to become a global commodity, it first had to catch on in one or more of Europe's seafaring imperial nations: Portugal, Spain, the Netherlands, Great Britain, and France. Only their merchants, planters, and seamen had the means to ensure that the drugs they valued became worldwide trade goods and cash crops.

Tobacco as a Model

Tobacco offers the clearest example of European adoption and global dissemination of a novel psychoactive drug. Tobacco use and cultivation had originated in South America and spread northward, reaching the upper Mississippi valley by 160 CE. It also had taken root in the Caribbean, where in 1492 two of Columbus's crew observed Taino Indians smoking tobacco. Later explorers and missionaries often described native smoking rituals. But in Europe, early interest in tobacco centered on its possible medical uses. The Seville physician Nicolas Monardes (1493–1588) recommended that tobacco be applied topically to aches and wounds; swallowed to kill worms; or chewed to alleviate hunger and thirst. Others valued it as an antidote to epidemics. Tobacco was much in demand when plague visited Europe's cities.

Tobacco also caught on among soldiers, sailors, and courtiers, including England's Sir Walter Raleigh (1552–1618). Begun as a pastime and continued as an addiction, nonmedical tobacco use proved

In the course of history many more people have died for their drink and their dope than have died for their religion or their country. • **Aldous Huxley (1894–1963)**

The tobacco plant in flower. Tobacco offers the clearest example of European adoption and global dissemination of a novel psychoactive drug.

controversial. Critics said it sickened and impoverished its enslaved users. The practice nevertheless continued to spread in taverns and brothels, and in distant lands visited by pipe-smoking sailors. Demand grew, and so did profits for cultivators. The Spanish introduced tobacco to the Philippines, where it became a cash crop after 1575. About 1600 sailors and merchants from Fujian Province, in southeastern China, took the plant back with them from the Philippines. Between about 1590 and 1610 the Portuguese introduced tobacco to West Africa, India, Java, Japan, and Iran. Subsequent diffusion from these places made tobacco a truly global crop.

Seventeenth-century clerics, physicians, and monarchs in lands as far separated as Great Britain and

China condemned the nonmedical use of tobacco. But even public executions of recalcitrant smokers failed to check tobacco's progress. By the end of the seventeenth century, prohibition had given way to regulation and taxation, as tobacco settled into a long career as a lucrative nuisance. It became a major source of tax revenue and, for European overseas empires, a mainstay of colonial agriculture, expanding through the African slave trade. The more the American plantations produced, the more Europeans and their reexport customers consumed. As with sugar, plantation agriculture increased supply and drove down the price. Chesapeake tobacco that had sold for as much as sixteen English pennies a pound in the early 1620s was bringing only one penny by 1670. Practically everyone could afford to smoke, chew, or snuff the drug—the method of consumption varying by region, gender, class, and shifting fashion.

Advantages of Drug Commerce

The story of tobacco repeated itself, with variations, for all the major global drugs. When Europeans discovered a novel psychoactive substance (or learned to manufacture one, as in the case of distilled spirits) they always investigated possible medical uses. This aspect of drug dissemination—doctors debating indications, doses, and side effects—seldom caused public alarm. Several therapeutic breakthroughs, such as the 1884 discovery of cocaine's local anesthetic properties, won universal approval. Controversy arose only when a pattern of nonmedical use emerged, as in England's early eighteenth century gin-drinking epidemic, the "luxurious" use of opium by the idle rich, or, in the age of synthetic and semisynthetic drugs, self-intoxication with barbiturates, heroin, and amphetamines.

For most of eighteenth and nineteenth centuries, government officials tolerated drug abuse and poisoning as unfortunate by-products of a lucrative commerce. Drugs were, in many ways, ideal products. Because they were quickly consumed, regular users had to constantly replenish their supplies. Because they caused tolerance—larger and larger doses were

This nineteenth-century drawing titled *Selling the Deadly Drug* depicts Western attitudes toward both opium and China.

necessary to achieve the same effect—sales volume tended to increase over time. And because drugs addicted at least some users, demand was relatively inflexible. In the early days of the 1849 California Gold Rush, tobacco sold for close to its weight in gold. Entrepreneurs rushed supplies from Honolulu and other ports to San Francisco, whose warehouses soon bulged with tobacco.

Alcohol and tobacco were ideal barter goods. Merchants traded them for native labor and for such products as sandalwood, trepang (sea cucumbers), copra, and peltries (furs and skins). The early modern fur trade, a global enterprise that tied Europe's cities to the remotest backwoods of Siberia and the Americas, was in essence also a drug trade, with profits running as high as 400 percent on the watered spirits supplied to natives. Alcohol and tobacco proved just as useful in acquiring African slaves. Between 1700 and 1830 perhaps one in every four slaves imported from Luanda and Benguela to Brazil was paid for with rum. The slave/plantation/drug complex became a sort of economic perpetual-motion machine. Slaves grew tobacco and sugar; sugar was manufactured into rum;

tobacco and rum (as well as coffee and cacao) helped pay for more slaves, who raised more drug crops.

Political elites profited from the growing drug commerce through taxation. Imperial Russia, for example, essentially paid for its military by taxing alcohol. Colonial administrators in Africa and Asia depended on alcohol taxes, often supplemented by opium revenues. They periodically auctioned the exclusive right to sell opium (the "opium farm") to the highest bidder, usually a syndicate of Chinese merchants. During the nineteenth century Singapore derived half its revenue in this manner. The French profited from a similar commerce in Indochina. In 1945, when Ho Chi Minh (1890–1969) officially declared Vietnamese independence, he specified the opium and alcohol traffic as among the many imperialist crimes the French had committed against his people.

Restriction and Prohibition

Revulsion against imperial drug profiteering was one important reason for the worldwide movement to restrict or prohibit drug trafficking. The reformers

Universal approval of cocaine's local anesthetic properties warranted its use in soft drinks (Coca-Cola), cough medicine, and the "cocaine toothache drops" in this 1885 advertisement.

initially concentrated on China, where nationalists and Christian missionaries had long been concerned with opium smoking. The problem originated with opium imports from British India in the eighteenth and nineteenth centuries. Though forbidden by Chinese imperial edict, the import trade flourished, and acquired legal status after the British prevailed in the Opium Wars of 1839–1842 and 1856–1858. Chinese domestic production rose even faster than imports; by the early twentieth century the Chinese were growing most of their own opium in vast poppy fields. The traffic threatened the nation's health, morale, and productivity. Chinese officials wanted it stopped. So did Britain's reformist and temperance-minded Liberal government, which came to power in 1906. The following year, 1907, the British began to phase out Indian opium exports, conditional upon the Chinese eliminating domestic production at a similar rate. In 1913 the India-China opium trade officially came to an end. The initial (if imperfect) success of this joint effort set a precedent for supply control, which became the central object of drug diplomacy for the rest of the twentieth century.

By 1912 diplomats from Britain, the United States, and other nations had hammered out the Hague Opium Convention, a treaty aimed at limiting the manufacture and consumption of opium and coca-based drugs to the amount required for medical purposes. At first Germany, whose pharmaceutical industry could produce large amounts of narcotics, put off signing the agreement. But, after defeat in World

War I (1914–1918), Germany and its ally Turkey, a leading opium producer, were required to ratify the Hague Convention as part of the peace process. Over the next half century diplomats and drug-control bureaucrats negotiated further amendments and treaties, the upshot of which was tighter narcotic production and export regulations. The 1971 Psychotropic Substances Convention brought several new categories of drugs, including hallucinogens, amphetamines, and barbiturates, into the international control regime.

None of this diplomacy ended international drug trafficking, though it did reduce its volume and alter its character. Criminal syndicates and guerrilla armies played an increasingly important role in the clandestine manufacture and illegal distribution of regulated drugs. Illicit trafficking became concentrated in chaotic or weakly governed regions, such as China between the world wars or Colombia in the late twentieth century. Protracted civil war was good for the illicit drug business. Contending factions knew they could acquire cash for weapons by protecting local growers and smugglers, and appropriating a share of their profits.

The international movement to rein in the narcotic traffic was part of a larger campaign against the abuse of psychoactive substances. By the late nineteenth and early twentieth centuries the world was awash with manufactured drugs, including cheap spirits and mass-produced cigarettes. A growing body of medical evidence testified to the toxic effects of these substances, both for their users and for children exposed

in the womb. Urbanization and industrialization had made intoxication more wasteful and dangerous. No one wanted drunken operators around heavy machinery, or behind the wheels of the growing fleet of motor vehicles. The new industrial realities also gave rise to a cosmopolitan progressivism, a conviction that governments should restrain economic activity that generated inordinate social costs. To many progressive reformers, poisoning people for profit fell into the same category as rapacious monopoly, unrestrained industrial pollution, and adulterated food. All merited government suppression.

What made drug suppression tricky was that exceptions had to be made for legitimate medical use. Even in the United States during Prohibition (1920–1933), medicinal alcohol was exempted and widely available through prescription. By the last third of the twentieth century the problem of medical exemption was commonly resolved by a system of “scheduling.” That meant sorting drugs into legal categories according to their medical benefits, toxicity, and addiction potential. The most restrictive category, which included hallucinogens such as LSD or (in some nations) cannabis, amounted to prohibition. Other categories ranged from tight controls on manufacturing and distribution for drugs like methadone, a synthetic opiate, down to simple prescription requirements for drugs of lesser abuse potential. Unscheduled drugs such as caffeinated beverages, tobacco, and alcohol were regulated, if at all, through tax policy and restrictions on advertising or sales to minors.

The Double Standard

The most anomalous feature of the modern control system was that it privileged tobacco and, at least outside of Islamic lands, alcohol, despite the fact that tobacco and alcohol were as harmful as many of the drugs subject to stricter controls. As lung tumors became the world’s most common form of cancer, critics complained that it made no sense to outlaw marijuana while permitting worldwide sales to pass, in 2000, a record 15 billion cigarettes a day. In fact, given tobacco’s role as a “gateway” drug (those who smoked

tobacco were far more likely to experiment with other drugs), there wouldn’t have been as much marijuana use if cigarettes hadn’t been so readily available.

Though irrational in public health terms, tobacco and alcohol’s underregulation made sense in economic and sociological terms. The smaller and more deviant a drug-using population, the easier it was to impose and maintain restrictive legislation. The larger and less deviant, the harder it was. By the early twentieth century, nonmedical cocaine use was widely associated with prostitutes and, in North America, with renegade black men. The places that grew most of the world’s coca, Peru and Java, were poor and politically inconsequential. That simplified the task of international control. The same couldn’t be said of alcohol production, then an important industry on every continent except Antarctica. In the early twentieth century, one in every eight Frenchmen derived income from some aspect of the alcohol business. The scale of potential opposition was one important reason why politicians generally preferred alcohol taxation to stricter forms of control. That most of these politicians enjoyed alcohol themselves was another factor, elites being disinclined to outlaw their own vices.

The popularity of cigarettes conferred similar advantages on tobacco companies, at least until the late twentieth century, when the educated classes in Western societies began shunning their products. The tobacco companies’ wealth nevertheless permitted them to pursue a sophisticated strategy to save their business in the face of damning medical evidence. They hired public relations experts to obfuscate the health issue; deployed lobbyists to block, delay, or water down antismoking measures; advertised cigarettes as cool products to attract new teenage smokers; and aggressively expanded in developing nations, many of which lacked tobacco marketing regulations. In 1999 and 2000, World Health Organization (WHO) investigators found that 11 percent of Latin American and Caribbean school children between the ages of thirteen and fifteen had been offered free cigarettes by tobacco industry representatives. In Russia the figure was 17 percent, in Jordan 25 percent. Outrage

The voodoo priest and all his powders were as nothing compared to espresso, cappuccino, and mocha, which are stronger than all the religions of the world combined, and perhaps stronger than the human soul itself. • Mark Helprin (b. 1947)

at such tactics, coupled with alarm over the health consequences of the cigarette pandemic, prompted an international anti-tobacco movement, not unlike the narcotic control campaign of a century before. To date the principal diplomatic achievement of this movement has been the WHO's 2003 Framework Convention on Tobacco Control. This agreement commits signatories to such goals as advertising restrictions, smoke-free environments, and state-funded treatment for those trying to quit—an ambitious agenda in a world of 1.3 billion smokers.

The writings of W. E. B. Du Bois, including the first study of urban blacks in the United States, had a huge impact on African American communities during the 1900s. Du Bois believed in Pan-Africanism and played a major role in founding the NAACP. Although he left the United States for political reasons, he remained (and still does nearly fifty years after his death) an influential presence.

William Edward Burghardt Du Bois was one of the most important African American leaders in the United States in the first half of the twentieth century. He made significant contributions as a journalist, sociologist, historian, novelist, pamphleteer, civil rights leader, and teacher. Among his many publications are sociological studies as well as studies of the slave trade (1896), John Brown (1909), and Reconstruction (1935).

Du Bois was born on 23 February 1868, in Great Barrington, Massachusetts. In 1884, he graduated from Great Barrington High School as valedictorian of his class. In 1888, Du Bois graduated from Fisk College in Nashville, Tennessee. It was while in Tennessee that Du Bois first experienced overt racial discrimination. Du Bois earned a second bachelor's degree (1890) and a master of arts degree (1892) from Harvard University. From 1892 to 1893, he studied at the University of Berlin, where he was greatly influenced by the socialist scholar Eduard Bernstein (1850–1932). Du Bois remained sympathetic to Marxism for the rest of his life.

In 1895, W. E. B. Du Bois was awarded the first doctorate to be granted to an African American by Harvard. His doctoral dissertation, *The Suppression*

of the African Slave Trade to the United States of America, 1638–1870, was published in 1896. It constitutes a pioneering application of economic analysis to history. Previous studies of slavery had given little attention to slavery's indissoluble connection to the cotton market.

After receiving his doctorate from Harvard, Du Bois served as a professor at Wilberforce University (1894–1896) and as an assistant instructor of

Photograph of W. E. B. Du Bois, the U.S. sociologist and writer, taken in Atlanta, Georgia, in 1900. New York Public Library.

Du Bois in the office of *The Crisis*. His editorials brought about changes in public policy, including the creation of a federal work plan to benefit African American veterans.

sociology at the University of Pennsylvania (1896–1897). But he is best known for his long association with Atlanta University, where he was a professor of economics and history from 1897 to 1910 and served as the chair of the sociology department from 1934 to 1944.

Between 1897 and 1914, Du Bois completed multiple sociological investigations of African Americans, including *The Philadelphia Negro: A Social Study* (1899), which is the first case study of an urban African American community ever conducted in the United States.

Du Bois's views on civil rights clashed with those of another prominent African American leader, Booker T. Washington (1856–1915). Washington urged African Americans to accept discrimination for the time being and encouraged them to elevate themselves through hard work. At first, Du Bois agreed with Washington; he applauded the famous 1895 Atlanta speech in which Washington argued for “segregated equality.” But changes within African American communities militated against Washington's position as African American migration accelerated the growth of black ghettos. Du Bois addressed Washington's position in a chapter of his most widely known book, *The Souls of Black Folk* (1903), cogently arguing that

Washington's strategy could serve only to perpetuate the further oppression of African Americans.

The Souls of Black Folk also gave first expression to Du Bois's most abiding theoretical contribution to African American studies. He underscored the characteristic dualism of African Americans: “One ever feels his ‘two-ness’—an American, a Negro; two souls, two thoughts, two irreconcilable strivings; two warring ideals in one dark body, whose dogged strength alone keeps it from being torn asunder” (1996, 58).

In 1905, Du Bois founded the Niagara Movement. This small organization, which met annually until 1909, was seriously weakened by internal squabbles. Nevertheless, it is significant as the forerunner of the National Association for the Advancement of Colored People (NAACP).

Du Bois played a major role in founding the NAACP in 1909 and became the association's director of research. As founding editor of its magazine *The Crisis*, he wrote editorials that resulted in a number of changes to public policy: the admission of African Americans to officers' training schools, establishment of legal procedures against those accused of lynching African Americans, and the creation of a federal work plan to benefit African American veterans.

Herein lie buried many things which if read with patience may show the strange meaning of being black here in the dawning of the Twentieth Century. This meaning is not without interest to you, Gentle Reader; for the problem of the Twentieth Century is the problem of the color-line. • **W. E. B. Du Bois (1868–1963)**

Du Bois's nationalism took a variety of forms. He was a strong advocate of Pan-Africanism—a political ideology based on the belief that all people of African descent had common interests and should work together in a common struggle for freedom. In 1900, Du Bois served as an organizer of the first Pan-African Conference, which was held in London. He was also the architect of four subsequent congresses held between 1919 and 1927.

In addition, Du Bois was an advocate of economic nationalism. He asserted that African Americans needed to develop a separate “group economy” of producers and consumers. Others within the NAACP did not see it this way. Du Bois's ideas brought about an intense ideological split within the organization, and in 1934 Du Bois resigned from the NAACP.

After leaving the NAACP, Du Bois returned to Atlanta University, where he devoted the next ten years of his life to teaching and research. In 1940, he founded the magazine *Phylon: The Atlanta University's Review of Race and Culture*. He also produced two major books: *Black Reconstruction* (1935) and *Dusk of Dawn* (1940). *Black Reconstruction* provided an innovative and exhaustive treatment of a pivotal period in African American history. *Dusk of Dawn* was autobiographical and recounted Du Bois's role in the civil rights struggle.

Following a decade of teaching at Atlanta University, Du Bois returned to the NAACP, where he held a research position from 1944 to 1948, but this affiliation ended in yet another bitter debate.

In the 1890s, Du Bois had been an outspoken supporter of capitalism, publicly urging African Americans to support African American businesses. By 1905, however, he became thoroughly convinced of the advantages of socialism. He joined the Socialist Party in 1912 and remained sympathetic to socialist ideals for the rest of his life.

After 1948, Du Bois moved further leftward politically. He began to identify with pro-Russian causes and was indicted in 1951 as an “unregistered agent for a foreign power.” Although acquitted of all charges, Du Bois became increasingly disillusioned with the United States. In 1962, he renounced his American citizenship and moved to Ghana, where he was to serve as editor in chief of the *Encyclopedia Africana*. The encyclopedia was never completed.

W. E. B. Du Bois died on 27 August 1963, in Accra, Ghana. The majority of his personal papers are archived at the University of Massachusetts at Amherst.

Dutch East India Company

The Dutch East India Company (VOC), founded in 1602, consisted of sixty companies aimed at monopolizing the spice trade, expanding Dutch colonial influence, and reducing competition from other commercial powers. The VOC did not merely monopolize world trade; it acted as the sole representative of Dutch political power in the East Indies for nearly two hundred years.

Historians have identified the Dutch Republic as the first modern economy, while the Dutch East India Company (or VOC, the acronym for *Verenigde Oost-Indische Compagnie*) has, deservedly or not, been styled the first modern corporation. In the context of the Eighty Years' War (1568–1648), the general expansion of trade and shipping, and, to a lesser extent, the missionary impulse of Calvinism, Dutch overseas expansion was spurred by a powerful combination of politico-economic, commercial, and religious motivations. The first shipping to Asia in 1595 was followed by the creation of “pre-companies” in various cities of the northern Netherlands trading to the East. To curb internal competition and forge a military-diplomatic tool against the Spanish and Portuguese colonial possessions, these pre-companies were merged into a United East India Company. On 20 March 1602, the States General issued a charter, which would be continuously renewed until 31 December 1799, when the possessions of the VOC were taken over by the Dutch government.

In the “age of mercantilism,” the VOC was given a monopoly on all shipping from Africa’s Cape of Good Hope through the Strait of Magellan at the tip of South America, effectively covering the entire

Indian Ocean basin. The board of directors, or *Gentlemen Seventeen*, consisted of eight representatives from Amsterdam, four from Zeeland (Middelburg), one from each of the four smaller chambers (Rotterdam, Delft, Hoorn, and Enkhuizen), and a final member selected by Zeeland or one of the smaller chambers. The charter also granted the company delegated sovereign powers, including the right to appoint governors, build forts, maintain armies and fleets, and conclude treaties with or wage war against indigenous rulers.

Merchant Ship of the Dutch East India Company (1782). Woodblock print of the Nagasaki School, published by Toshimaya. The Dutch East India Company was one of the earliest European companies to trade with Japan.

The emblem of the Dutch East India Company, possibly the first corporate logo, was used on company-issued items such as cannons, coins, and flags.

A central Asian rendezvous and trade emporium was established at Jakarta, renamed Batavia, on the island of Java in 1619. Batavia was the seat of the High Government, the Governor General, and the Council of the Indies, coordinating activities of the company settlements in the East. The VOC divided its trading operations in Asia into three categories, with their relative significance indicated by their respective designation. The core consisted of spice-producing areas or trade emporia, such as the “governments” of Ambon, Banda, Cape of Good Hope, Coromandel, Makassar, Northeast Coast of Java, Taiwan, and Ternate, where the company enjoyed trade as an outcome of its own conquest. A second category contained those regions, such as the “commandments” of Malabar and the West Coast of Sumatra, where the company conducted trade through exclusive contracts. The third category consisted of economically important establishments under a director, including Bengal, Surat, and Persia, parts of powerful indigenous realms such as Mughal India (1526–1857) or Safavid Persia (1501–1722/1736), and peripheral establishments under a resident, head, or chief, such as Banjarmasin, Ligor, or Tonkin, where trade was conducted alongside other merchants.

Before the Industrial Revolution, trade between Europe and Asia was characterized by a structural trade

imbalance, following a “bullion for goods” model. (See table 1.) Precious metals served as the lubricant of the early-modern world economy with important political, socioeconomic, demographic, and cultural ramifications, interacting with regional and local processes of state formation, social stratification, economic development, population movements, and intellectual-religious changes.

The economic history of the VOC can be divided into three distinct periods: a monopolistic phase (1600–1680), determined by the acquisition of monopolistic or monopsonistic (market situation in which the product or service of several sellers is sought by only one buyer) positions in various commodities (pepper and fine spices) and markets (Japan); a competitive phase (1680–1740), dominated by less profitable, nontraditional products, such as textiles, coffee, and tea, available on the relatively open markets of India, Arabia, and China; and disengagement and decline (1740–1800), marked by the commencement of the era of Franco-British global wars and a distinct decline in terms of the volume of Dutch trade and shipping. (See tables 2 and 3.)

The Dutch claim in North America began in 1609, when the Britain’s Henry Hudson, in service to the Dutch East India Company, entered New York Bay and ascended the river that now bears his name.

Historians have pointed to a number of factors contributing to the eventual demise of the company. Previous scholarship criticized nontransparent

bookkeeping practices, the narrow financial basis of the VOC and the resulting dependency on outside capital, failing entrepreneurship and lesser quality of

company servants, lack of coordination between the various levels of administration, and increasing corruption among VOC officials in Asia. More recently, however, scholars have stressed changing consumption patterns for Asian products in Europe, declining profits from inter-Asiatic trade partly related to the decline of the Mughals (after 1707), the fall of the Safavids (1722), the increasingly restrictive policies of Tokugawa Japan after 1685, and the disruptions caused by the Fourth Anglo-Dutch War (1780–1784). Similar to the English East India Company some fifty years later, the VOC fell victim to the ongoing processes of territorialization, especially on Ceylon and Java, and subsequent rising administrative overhead costs, along with the growing competition of British country traders. In the nineteenth century merchant capitalism and chartered companies were superseded by the overseas projection of industrial capitalism and the nation-state.

Dutch Empire

In 1602 the founding of the Dutch East India Company, which became the largest company in the world at the time, literally created an empire. The empire focused mostly on trade, however, and less on colonization; many Dutch colonial possessions fell to the British in the eighteenth and nineteenth centuries. Rebellion from Japanese-occupied Dutch East Indies during World War II ultimately brought the empire to its end.

Toward the end of the sixteenth century, Dutch ships started to explore the waters beyond Europe. Because of their rebellion against their Habsburg rulers, the Dutch no longer were able to operate as traders in the Portuguese and Spanish overseas empires or obtain non-European products in the Habsburg-controlled Iberian ports. In order to reduce the risks of conducting trade in Asia, the United East India Company (Vereenigde Oost-Indische Compagnie or VOC) was founded in 1602.

United East India Company (VOC)

The VOC was the first commercial venture in the world financed by anonymous shareholders with the aim of conducting business over a lengthy period of time, not just financing one trip or conducting business for one year. Within six months about 6 million guilders were collected. The company was made up of six local chambers, and according to its share in the capital outlay, each chamber was allowed to send representatives to the seventeen-member board of directors. The company received a monopoly from the government for trade and the right to declare war

and conclude treaties with individuals and states in the whole of Asia.

During the first two decades of its existence, the VOC needed government subsidies to stay afloat, but after 1620 its activities were increasingly more profitable. Trading between the various regions in Asia accounted for most of these profits. In 1619 the city of Batavia (now Jakarta) was founded as the pivot in the trade between the Dutch Republic and its trading partners in Asia. The governor general in Batavia concluded treaties with local rulers for the exclusive delivery of spices such as pepper, nutmeg, cinnamon, and cloves. In addition the company traded in opium, Chinese porcelain, tea, silk, and Indian cotton cloths. In order to obtain these goods, the company sent large amounts of cash to Asia.

Over time the VOC grew to become the largest company in the world, employing more than 40,000 persons at the height of its existence. Yearly, more than sixty East Indians left the Netherlands for a year-long journey to Batavia, using the Dutch colony at the Cape of Good Hope as a stopover. During the course of the eighteenth century, however, competition from the British East India Company, the French, and even the Danes took business away from the VOC. In order to keep its shareholders and bondholders happy, the company started to borrow money in order to pay dividends. In spite of regulations, most of the company's employees in Asia conducted trade on their own behalf, which was also detrimental to the company's well-being, forcing it into bankruptcy. In 1799 the Dutch state dissolved the VOC and assumed the sovereignty over the company's possessions in Asia and at the Cape of Good Hope.

The popular view that free trade is all very well so long as all nations are free-traders, but that when other nations erect tariffs we must erect tariffs too, is countered by the argument that it would be just as sensible to drop rocks into our own harbors because other nations have rocky coasts. • **Joan Robinson (1903–1983)**

West India Company (WIC)

The early success of the Dutch East India Company was a strong stimulus to create a similar company for the trade and colonization in the Atlantic. In 1621 the West India Company (The West-Indische Compagnie or WIC) was founded. In contrast to the VOC, the WIC took a long time to collect sufficient operating capital. Most merchants did not invest as they felt that the company would be used by the Dutch state as an instrument of maritime warfare against Spain rather than as a profit-seeking venture. Like the VOC, the WIC was organized in chambers, but in the course of the company's history, its policies became more and more fragmented. The Zeeland chamber began to administer some parts of Guiana exclusively, whereas the Amsterdam chamber concentrated on New Netherlands in North America and the Dutch Antilles. In 1628 all chambers were allotted exclusive trading rights in separate areas along the coast of West Africa. This process of fragmentation was strengthened by the issuing of private freehold estates, called *patroonships*, in New Netherlands and in the Caribbean. A consortium, in which the WIC participated as only one of the shareholders, owned the Caribbean plantation colony of Suriname, conquered in 1667. Private merchants who received land grants within the company's territory were usually connected to, or even directors of, one specific WIC chamber.

At the beginning the WIC played an important role in the Dutch maritime trade. Around 1650, when the company still governed part of Brazil and New Netherlands, the total value of the imports into the Dutch Republic amounted to about 60 million guilders, of which nearly 18 million came from Brazil, Africa, the Caribbean, and North America. During the second half of the seventeenth century, the loss of Brazil and New Netherlands, the application of the Navigation Acts in the British colonies and similar protectionist legislation in the French colonies, and the declining opportunities for Dutch privateers reduced the volume and value of the Dutch Atlantic trade. Around 1650, estimates put the yearly number of Dutch ships operating in the Atlantic at around 250. During the eighteenth century that average had declined to about 140. In addition to the triangular slave trade from Europe to west Africa, then on to the New World and back again to Europe, the WIC ships traded in American and African produce such as Brazilian wood, hides, ivory, sugar, tobacco, and cacao.

The WIC concentrated on trade, not colonization. The total number of Europeans in the colonies and trading establishments of the company never surpassed 20,000 at any one time. That suggests that it must have been more profitable to send young men on a temporary basis to tropical Asia than to settle them as colonists in New Netherlands and the Cape colony.

The Dutch West India Company was not interested in exporting the Dutch language or the official brand of Dutch Protestantism. The governors of the various Dutch colonies and trading forts were well aware of the fact that only religious and cultural tolerance could prevent internal strife among the many non-Dutch nationals.

After 1734 the WIC became a "body without a soul." Private consortia governed the two most important Dutch plantation colonies, Suriname and Berbice (in present-day Guyana). The company was left with the administration of the Dutch possessions on the African coast, the Dutch

An early drawing of the Dutch colony of New Amsterdam.

A fleet of Dutch merchant ships in the sixteenth century. The empire focused more on trade than on colonization.

Antilles, and two small plantation colonies on the South American mainland, Essequibo and Demerara. Its top-heavy apparatus at home did not change: the national and local directorships had become part of the job circuit within the Dutch oligarchy. Private Dutch traders did increase the volume of the trade in slaves and tropical cash crops, but the Dutch were unable to profit from the explosive growth of the Atlantic economy after the War of American Independence. In 1791 the second WIC was abolished, and the Dutch Republic itself became a colonial power.

The Netherlands as a Colonial Power

During the period 1795–1816, virtually all the Dutch colonial possessions fell into the hands of the British. Eventually, the Dutch East Indies, Suriname, and the Dutch Antilles were handed back, but not the Cape colony, Ceylon, Demerara, Essequibo, and Berbice. In 1870 Britain bought the Dutch forts on the Gold Coast.

In the East the Dutch colonial government could not generate sufficient income to pay for the administration and defense. In order to increase the colonial revenue, a system of forced cropping was introduced in 1830, by which the Indonesian villagers would cultivate a part of their lands with coffee and sugar to be delivered to the colonial government as a tax in kind. This system was a financial success, and soon the island of Java produced so much revenue that the major part of this income could be transferred to the treasury in the Netherlands. In 1860 both the cultivation system in

the East as well as slavery in the West were abolished as the prevailing liberal ideology in the Netherlands had become opposed to forced or slave labor. After 1870 investment and private land ownership by European entrepreneurs increased, and Dutch control was extended to all of the islands of the Indonesian archipelago. In Aceh (North Sumatra) the Dutch met with fierce resistance, and it was not until 1913 that the region was brought fully under Dutch control.

In the Dutch Caribbean, slavery was not abolished until 1863. The belated emancipation of 40,000 colonial slaves was due to the fact that there was no strong abolitionist lobby in the Netherlands and that until 1860 the liberal ideology in economic matters did not have many adherents, nor was tax money readily available to compensate the slave owners. It was the revenue derived from the cultivation system in the Dutch East Indies that tipped the balance. After the ending of slavery, the Dutch instituted a ten-year period of apprenticeship (1863–1873) and then started to import 30,000 indentured laborers from British India (1873–1916) and a similar number from Java (1890–1939). As the Dutch Antilles housed no large-scale plantations, their freedmen were exempt from apprenticeship, and none of the islands imported indentured labor. At the beginning of the twentieth century, the economy of the islands received a strong boost from the construction of oil refineries. Similarly, Suriname experienced economic growth by allowing the American-owned SURALCO Company to mine its aluminum ore. During World War II, the

aluminum production in Suriname and the oil refineries on the Dutch Antilles were of such importance to the allied war effort that the United States and the United Kingdom took over the defense of these colonies with the consent of the London-based Dutch government in exile.

End of the “Empire”

In 1942 the Japanese occupied the Dutch East Indies and collaborated with those Indonesian politicians who were in favor of independence. Its 40,000 Dutch colonists were put in camps. After the Japanese had surrendered in 1945, the Indonesians promulgated the independent Republic of Indonesia, while the Dutch tried to restore their prewar colonial rule. In spite of severe shortages at home caused by the ravages of the German occupation, the Dutch drafted a considerable army to fight the Indonesian Republic. However, the U.S. government was in favor of Indonesian independence and threatened to cut off Marshall Plan aid to the Netherlands. The Dutch gave up their efforts to restore colonial rule, and on 17 August 1949, the Republic of Indonesia, with the exception of the eastern part of New Guinea, which was not transferred to Indonesia until 1963, became a sovereign state.

In the wake of the achievement of independence by Indonesia, Suriname and Dutch Antilles were given self-government in 1948. In 1954 a Dutch Commonwealth Statute stipulated that the Netherlands, the six Dutch Antilles (Curaçao, Aruba, Bonaire, Saint Martin, Saint Eustatius, and Saba), and Suriname would be equal partners, have internal self-government, and share their foreign relations and defense. Over time the disadvantages of this arrangement increased as about 30 percent of the population of the Dutch West Indies moved to the Netherlands, while at the same time the Dutch government spent large amounts in aid subsidizing the budget of these former colonies. In 1975 the Dutch succeeded in granting independence to Suriname by providing the 400,000 inhabitants of the former colony with 4 billion guilders in aid. The six Dutch Antillean islands refused a similar offer. The Dutch

Antilles prefer to continue their membership in the Kingdom of the Netherlands, but some of the islands prefer to have a direct link with The Hague rather than an indirect one through the common inter-island council in Willemstad on Curaçao. The Netherlands cannot change its relationship with the Dutch Antilles, such as instituting a barrier for immigrants, as the Commonwealth Statute demands that all constituent members of the Dutch Kingdom agree to its annulment.

Early Modern World

The term *early modern world*, though often debated by historians, generally refers to the years between the fifteenth century and the late eighteenth century. This era saw a huge increase in human population, as well as the discovery and expansion of the world's global sea passages. This development facilitated analysis across national boundaries and recognized that time unites people as powerfully as place.

Historians sometimes refer to the era between the premodern (or medieval) and late modern eras as the “early modern world.” The word during this time was increasingly united by the projection of European power abroad, especially in the Americas. Although early modern Europeans still had little knowledge of, let alone influence over, the inland regions of Africa and Asia, the links engineered and dominated by Europeans made all the world a stage for fundamental historical processes.

Historians debate, or pass over in silence, the problem of determining the precise starting and ending dates of the early modern world and have produced only the vaguest consensus. Roughly, the era of the early modern world began during the fifteenth century with the Timurid (relating to the Turkic conqueror Timur) and Italian cultural renaissances. The year 1405 serves as a convenient starting date because it marks not only the death of Timur, the last great Central Asian conqueror to join farmers and nomads into a single empire, but also the first of the naval expeditions to the “Western oceans” by the Chinese admiral Zheng He (c. 1371–1435). The era might be taken to end in the late eighteenth century with the French and industrial revolutions, both European events of global consequence

in the late modern world. The uncertainty of this periodization derives in part from the concept of an early modern Europe, with its own uncertain chronological boundaries, and in part from the unconsidered way in which both phrases entered historical scholarship.

Origins of the Concept

Although conceptually the phrase *early modern world* is an extension of *early modern Europe*, the initial histories of both phrases have some surprises. The earliest known appearance of *early modern world* occurs in Willard Fisher’s “Money and Credit Paper in the Modern Market” from *The Journal of Political Economy* (1895). Although Fisher writes, “We all know that the system of bank credits and bank money, which was introduced into the great commercial centers of the early modern world, has now attained a quite marvelous development” (1895, 391), the geographical sense of his statement is strictly, if implicitly, European. On the other hand, the phrase *early modern Europe* first shows up twenty years later, in Dixon Ryan Fox’s “Foundations of West India Policy” in *Political Science Quarterly* (1915). Fox remarks, “It was now realized by students of colonial history that in the Caribbean [the “West India” of the article’s title] might best be traced the application of those principles which formed the working basis for the old empires of early modern Europe” (1915, 663). Ironically, the phrase *early modern Europe* first appeared in the Caribbean, in the global context of colonialism, in an article advocating trans-Atlantic history. In their debuts each phrase bore something of the other’s sense.

Fox’s usage was an anomaly, and when the phrase *early modern Europe* arrived in Europe, it had come

to stay. The phrase *early modern world*, however, for decades would imply *world* to mean, in an indefinite way, immediate rather than global surroundings; because this historical scholarship dealt with European subjects, the “early modern world” was in fact “early modern Europe.” The early modern world became global only with C. F. Strong’s grammar-school textbook *The Early Modern World* (1955) and S. Harrison Thomson’s 1964 review of J. H. Parry’s *The Age of Reconnaissance*, in which Thomson uses the phrase to describe the “story of the successive expansion of European venture, from Africa to the reaches of the Indian Ocean by Arabs and Portuguese by sea, the movement westward to the Americas and the early transition from discovery to fishing, trading, and exploitation” (1964, 188).

The first considered analysis of the early modern world came after the posthumous publication of Joseph Fletcher’s article “Integrative History” in 1985. Subsequent analysis has tended to adopt either a deductive or an inductive approach.

Deductive Approach

A deductive approach to the early modern world compares premodernity and late modernity, imagines the characteristics necessary to bridge the two stages, and only then seeks confirmation of them in the historical record. This approach assumes the existence of a modernizing trajectory, which the early modern world shared with (and perhaps inherited from) early modern Europe.

Informed by a Marxist perspective, the essentials of the early modern world would highlight transitions from feudal to bourgeois, from serfdom to wage-earning proletariat, and from local subsistence to regional market economies. A functionalist understanding of modernity, of the sort theorized by the German sociologist Max Weber (1864–1920), the U.S. sociologist Talcott Parsons (1902–1979), or the French sociologist Emile Durkheim (1858–1917), explains social phenomena in terms of their ability to fulfill social needs and broadens this base beyond the mode of production. Here the critical shifts would

be from belief in miracles to belief in science, from household-based craft production powered by muscle, dung, water, and wood to factory-based mass production powered by electricity and fossil fuels, and from government justified by tradition to government consciously invented.

Even in the context of early modern Europe critics challenge the effectiveness of a deductive approach by condemning its implication of an inevitable progress from premodernity to modernity. A deductive approach takes little cognizance of the possibilities of various starting points, different destinations, and particular paths. In some twentieth-century cases the transition to modernity was less a progression than a violently dramatic change. When expanded to a global context this approach becomes not only teleological (assuming a design or purpose in history), but also artificially Eurocentric.

Inductive Approach

Rather than specify theoretical factors to be sought in the time period, an inductive approach examines what happened in different places and extracts from what happened a set of common features. Although such an approach removes the theoretical obstacle of a modernizing trajectory, the historian is left with the Herculean task of specifying processes that united all, most, or many of the world’s peoples. Such an approach need not focus on Europe, nor need it measure the success of various regions in terms of their progress along Europe’s path.

How closely do the rough chronological parameters suggested here match the conventional historiographies (the writings of history) of the various regions outside Europe? Traditional periodizations in African and American history are directly linked to European expansion. Marked by a European presence that could not yet dominate the continent, an early modern Africa might last from the Portuguese capture of Ceuta, a port on the Moroccan side of the Strait of Gibraltar (1415), until the development of quinine and steamships in the nineteenth century. The first Niger steamship expedition returned

In 2005 Lui Gang, a Chinese collector, discovered this 1763 Chinese map of the world. Its unidentified author claimed to have copied it from a 1418 map used by Admiral Zheng He.

without casualties in 1854. An early modern America might stretch from the encounters of 1492 until the period of independence movements, from 1776 to the independence of Brazil in 1822.

An early modern India could begin with the fifth-generation descendant of Timur, Zahir-ud-Din Muhammad Babur, whose ancestry inspired him to conquer northern India. The Mughal Empire (1526–1857) he founded would rule effectively for two centuries; the British would take charge of its Delhi nucleus in 1803. An early modern Japan stretches from the unification efforts of Oda Nobunaga (1534–1582) to the end of the Tokugawa shogunate (the dictatorship of a Japanese military governor) in 1868. Other regional historiographies fit less naturally. Although the Ottomans' 1453 conquest of Constantinople (modern Istanbul, Turkey) was timely, the Chinese Ming dynasty (1368–1644) began too early and ended inconveniently in the middle of our early modern period. Worse, key modernizing

revolutions came late relative to the western European timetable—the Chinese revolution in 1911/12, the Russian Bolshevik revolution in 1917, and the Kemalist (relating to the Turkish soldier and statesman Kemal Atatürk) revolution in Turkey in 1923.

The actual use of the phrase *early modern* in the periodization of regional histories varies. Outside of Europe, it is most commonly used in Asia, especially in works on China, Japan, and, to a lesser extent, India. Historians of China sometimes extend the period into the twentieth century. Far fewer historians write of an *early modern Africa* or an *early modern Brazil*. This fact is due in part to the power of the word *colonial* to identify these time periods. Latin American periodization is so consistently divided into pre-Columbian, colonial, and national periods that there is no need for the phrase *early modern*, which should correspond to the middle, colonial period. In fact, the *early modern Mexico*

sometimes refers to the period immediately after independence.

The divergence of these traditional periodizations of regional histories, so often linked to high-level political history, should not surprise. The global historian in search of an early modern world can look beyond these periodizations to seek processes that enveloped wide swaths of the planet.

Development of Global Sea Passages

Nothing is more characteristic of the early modern world than the creation of truly global sea passages. Before 1492 the Americas remained essentially isolated from Eurasia. In 1788 the last key sea passage was completed by the first permanent settlement of Europeans in Australia. This passage also concluded the integration of the Pacific Ocean as a geographical concept, a process that began when the Spanish explorer Vasco Nuñez de Balboa became the first European to see the Pacific from America in 1513.

During the early fifteenth century the Europeans were unlikely candidates to fill the key role in this process of exploration. Portuguese exploration of the African coast was declining, and mariners were reluctant to sail out of sight of land. Even the overland excursions undertaken by Europeans had become more modest. Muslims still controlled southern Iberia, and in 1453 the Ottomans conquered Constantinople. Smart money would have looked rather at the Chinese admiral Zheng He, whose seven expeditions between 1405 and 1433 reached even the shores of eastern Africa. A change in Chinese imperial policy halted these expeditions, and the voyages that finally connected the world were directed by Europeans. In 1522 the survivors of the expedition of the Portuguese navigator Ferdinand Magellan completed the first circumnavigation of the globe, or perhaps that distinction goes to his Malay slave Panglima Awang, who may have reached his original home halfway through the voyage. During the following centuries a skilled captain and crew could navigate a ship from any port to any port and reasonably expect to arrive. In 1570 the Flemish cartographer Ortelius published

what has been described as the first modern atlas, the *Theatrum orbis terrarum* (Theater of the World); this comprehensive yet handy and inexpensive work enjoyed immediate success. By the end of the period the best-mapped region of the world would be China.

Global Demographic Interconnections

The world's population doubled during the early modern period, from approximately 374 million (1400) to 968 million people (1800). Although demographic data are limited, some patterns emerge. Rapid growth was punctuated by a seventeenth-century decline in Europe, Russia, Iran, Central Asia, China, and Korea—and recovery from this decline occurred globally, even in the Americas. The more populous regions tended to grow more rapidly.

The new global sea passages set the stage for a transatlantic “Columbian exchange” (the biological and cultural exchange between the New World and the Old World that began with the 1492 voyage of Christopher Columbus) and for a transpacific “Magellan exchange” of crops and disease pathogens that put the peoples of the world in a more direct demographic relationship than ever before. The arrival of American maize and potatoes in Eurasia, and later in Africa, facilitated an intensive agricultural, and thus demographic, growth, and the appearance of tomatoes in Italy and chili peppers in India had important dietary and culinary consequences.

Disease also became a global phenomenon. First appearing in Europe in 1494, venereal syphilis reached India four years later, and by 1505 it had outraced the Portuguese to China. The New World's isolation and limited biodiversity (biological diversity as indicated by numbers of species of plants and animals) did not afford its indigenous peoples the same immunities enjoyed by Europeans, who as children were exposed to a multiplicity of infections. Measles, smallpox, and other diseases brought by Europeans triggered a long-term demographic catastrophe. The indigenous population of central Mexico declined from 30 million in 1518 to 1.6 million in 1620—a

In 1154, the Muslim geographer Muhammad al-Idrisi created a map of the world called the “Tabula Rogeriana” for King Roger II of Sicily. The most accurate of its time, it was said to have been the basis for the map used by Christopher Columbus. Bibliotheque Nationale de France.

genocide unintended, misunderstood, and undesired by the Spanish who sought souls for salvation and laborers for their mines. Contact with the wider world wrought similar demographic calamities on other isolated peoples, including Pacific Islanders, Siberian tribes, and the Khoikhoi of southern Africa. Increased contacts distributed pathogens more evenly throughout the world and generally reduced susceptibility to epidemic disease.

Development of a Global Economy

The development of global sea passages integrated America into a truly global economy. Rapidly growing long-distance commerce linked expanding economies on every continent. Dutch merchants in Amsterdam could purchase commodities anywhere in the world, bring them to Amsterdam, store them safely, add value through processing and packaging, and sell them for profit. Intensive production fueled by the commercialism of an increasingly global market gave new importance to cash crops and sparked an unprecedented expansion in the slave trade.

The movement of manufactured goods from eastern Asia toward Europe and America created a chain of balance-of-trade deficits, which funneled silver from American mines to China. Regular transpacific trade developed during the decades after the founding

of Manila in the Philippines in 1571 and followed the same pattern: exports of porcelain and silks from China created a trade imbalance that sucked silver from the Americas and from Japan. Through military-commercial giants such as the Dutch East India Company (founded in 1602), European merchants disrupted traditional trading conditions in Africa and Asia to muscle into regional “country trade.” The expansion of settled populations, as well as the new ocean trade route alternatives to the Silk Roads that linked China to the West, contributed to the decline of nomadism. The agriculture of settled peoples supported large populations and tax bases that an efficient state could translate into continuing military strength.

Development of Large and Efficient States

The global trade in firearms and similar weapons contributed to the growth of large and efficient states, known as “gunpowder empires.” Expensive and complex, the most advanced weapons became a monopoly of centralized states, which employed them to weaken local opposition. During the mid-fifteenth century the king of France used artillery to reduce some sixty castles annually. Administrative procedures also became increasingly routinized and efficient. Ever

more abstract notions of state authority accompanied the evolution of new sources of legitimacy. From the Irrawaddy River in Asia to the Seine River in Europe, religious uniformity served to reinforce and confirm centralized rule. The ideal of universal empire was native to America, Africa, and Eurasia.

The early modern unification of England with Scotland and Ireland was paralleled throughout Europe. If in 1450 Europe contained six hundred independent political units (or more, depending on the criteria), in the nineteenth century it contained around twenty-five. About thirty independent city-states, khanates (state governed by a ruler with the Mongol title “khan”), and princedoms were absorbed into the Russian Empire. By 1600/1603 the Tokugawa shogunate had unified Japan. Fourteenth-century southeastern Asia had two dozen independent states that evolved into Vietnam, Siam (Thailand), and Burma (Myanmar) by 1825. The Mughals unified India north of the Deccan Plateau for the first time since the Maurya Empire (c. 324–c. 200 BCE). Unification was also an overture to expansion. In addition to an increasing European presence worldwide, Qing China (1644–1911/12) invaded Xinjiang, Mongolia, Nepal, Burma, and Formosa,

and during the seventeenth century Romanov Russia stretched out to the Pacific.

The new unities led relentlessly to new fragmentations and hierarchies, and resistance to such centralizing political forces was equally universal. During the century between 1575 and 1675, for example, uprisings occurred in China, Japan, India, Armenia, Georgia, Kurdistan, Ukraine, the Balkans, the German lands, Switzerland, France, Catalonia, Portugal, England, Ireland, and Mexico. At the end of the period, the French Revolution (1789) would enjoy global influence as the first revolution modern in its progressive, absolute, and sudden nature.

Intensification of Land Use

The concurrence of population growth, global markets, and aggressive states led to wider and more intensive use of land. Displacing or subordinating indigenous peoples, pioneers backed by aggressive states drained wetlands and cleared forests to create new lands for intensive commercial, agricultural, and pastoral regimes. (Similarly, commercial hunters pursued various species of flora and fauna to extinction for sale on a global market.) Oblivious to any land

The mid-sixteenth-century *Theatrum orbis terrarum* (Theater of the world) of Abraham Ortelius, a Flemish engraver and businessman, reflected an age of exploration, broadened commercial connections, and scientific inquiry. His map of Ireland, shown here, exemplifies the most modern mapmaking techniques of the period: precise geographic detail, beautifully rendered topographical symbols, and an abundance of place names.

claims held by indigenous peoples, states would offer pioneers low taxes in exchange for settlement and land rights. For example, the Mughal Empire provided land grants, Hindu merchants provided capital, and Sufi (Muslim mystic) brotherhoods provided leadership for the communities of Muslim pioneers who transformed the Bengal wetlands into a key rice-producing region. These efforts compensated for the extended disobliging weather patterns that plagued temperate zones throughout the Northern Hemisphere—a “little ice age” affecting climate throughout the early modern world.

Religious Revival

The most distinctive religious characteristic of this era was the global expansion of Christianity. Indeed, the impetus driving the creation of global sea passages was religious as well as commercial. The efforts of Catholic religious orders predominated—the great Protestant missionary societies would be founded only in the 1790s. Sufi brotherhoods such as the Naqshibandiyah expanded Islam in Africa, India, China, and south-eastern Asia. Tibetan Buddhism pushed into north-western China, Manchuria, Mongolia, Buryatia, and to Kalmikya, on the shore of the Caspian Sea, which remains today the only Buddhist republic in Europe.

The increased emphasis on orthodox and textual conventions of Latin Christendom’s Reformation had a parallel in the Raskol schism of the Russian Orthodox Church during the 1650s. Elsewhere, Muhammad ibn Abd al Wahhab (1703–1792) founded the Wahabbi movement to reform Sunni Islam under strict Qur’anic interpretation.

Many people believed that the era that historians call “early modern” would be the last. Franciscan apocalyptic thought inspired Columbus, and the belief that the god Quetzalcoatl would return from the East in a One Reed year may have led the Aztec sovereign Montezuma II to regard the Spanish conqueror Hernán Cortés and his comrades as divine envoys. A Jesuit at the court of Akbar in 1581 found the Mughal ruler open to the idea of the imminent end because that year was eleven years from the

thousandth anniversary of the Hijra, which was the journey the Prophet Muhammad took from Mecca to Medina in 622 CE. The Jewish Sabbatian movement expected the end of the world in 1666 and influenced apocalyptic thought even in Christian England. In late eighteenth-century central China the White Lotus Society awaited the return of the Buddha to put an end to suffering. All these developments might best be understood in the context of notions of history in which significant change was either absent—or sudden and awesome.

Outlook

Neither a deductive nor an inductive approach to the early modern world is entirely satisfactory. A deductive approach expects to see the entire world following a Eurocentric roadmap to modernization (one that Europe itself might not have followed). Indeed, renaming the period the *late traditional world*, the exact inversion of *early modern*, avoids both the teleology and the Eurocentrism. On the other hand, an inductive approach respects the diversity of historical experience, but this diversity itself can frustrate attempts to delineate a discrete list of unifying features.

If historians can tolerate the inconveniences of regional exceptions to every “global” process, the idea of an early modern world has its attractions. Although a perspective that twists the world around a European center is unproductive, the regions of the early modern world were increasingly named (in America) and mapped (as in China) by Europeans, even as they exploited, served, or collaborated with local peoples. Nevertheless, in its application beyond Europe the idea of an early modern world redresses the distortions of the Orientalist assumption of parochial, timeless, and conservative inertias unaltered by European expansion. It recognizes that peoples of the early modern era in some ways had more in common with each other than with their own ancestors and descendents—that time unites just as powerfully as place. It facilitates comparative analysis and abets inquiry that trespasses across national boundaries. It sees the entire world as a stage, not only for

comparative study, but also for the broadest possible analysis for a historian's scrutiny.

Earthquakes

Earthquakes are experienced as shockwaves or intense vibrations on the Earth's surface. They are usually caused by ruptures along geological fault lines in the Earth's crust, resulting in the sudden release of energy in the form of seismic waves. They can also be triggered by volcanic activity or human actions, such as industrial or military explosions.

Earthquakes can occur almost anywhere in the world, but most take place along particularly active belts ranging from tens to hundreds of miles wide. An earthquake's epicenter is the point on the Earth's surface directly above the source or focus of the earthquake. Most earthquakes are small and cause little or no damage, but very large earthquakes, followed by a series of smaller aftershocks, can be devastating. Depending on the location of the epicenter, these earthquakes can have particularly disastrous effects on densely populated areas as well as the infrastructure that supports them, such as bridges, highways, apartment buildings, skyscrapers, and single-family homes.

Earthquakes can destroy our built-up environments and the essential systems we rely on for our lives and livelihoods. They also have the potential to cause landslides and tsunamis (giant ocean waves that can flood and destroy coastal regions), both of which can have devastating effects on people and communities. The social and economic consequences of earthquakes can be vast, and recovering from them can take many years.

Early Explanations

Humans have come a long way in their understanding of the causes of earthquakes. At first, myths and

legends explained processes beneath the Earth's surface. Thinkers from the time of the Greek philosopher Anaxagoras (500–428 BCE) to the German canon and councillor Konrad von Megenberg (1309–1374) in the late Middle Ages believed, with slight variations, that air vapors caught in Earth's cavities were the cause of earthquakes: thus, Thales of Miletus (c. 625–547 BCE), the founder of Ionian natural philosophy, was among the first to attribute earthquakes to the rocking of the Earth on water. The Greek philosopher Anaximenes of Miletus (585–526 BCE) thought that periods of dryness and wetness were responsible for earthquakes. Aristotle (384–322 BCE) described earthquakes as the consequence of compressed air captured in caves; his ideas were used to explain meteorological phenomena and earthquakes until the Middle Ages. Moved by the devastating earthquake at Pompeii and Herculaneum on 5 February 62 (or 63) CE, the Roman statesman and philosopher Seneca (4 BCE–65 CE) backed Aristotle's thinking. Plinius (23–79 CE), the Roman historian and author of *Historia naturalis*, considered earthquakes to be underground thunderstorms.

When classical antiquity was rediscovered by the Christian Occident around 1200, significant parts of Greek ideology were merged with Christian ideas. Albertus Magnus (1193–1280), a German scientist and philosopher, supported the study of the writings of Aristotle and Arabic and Jewish commentators. His own works made an outstanding contribution to the development of the sciences. Georgius Agricola (1494–1555), a German humanist, physician, and mineralogist, believed that earthquakes were the consequence of a subterranean fire ignited by the sun. The long-lasting hypothesis of a central subterranean

fire, proposed by the Greek philosopher Pythagoras (570–500 BCE), was revived in the book *Mundus Subterraneus* by German scholar Athanasius Kircher (1601–1680).

During the eighteenth century scientists became increasingly convinced that no natural phenomenon was unexplainable, thus an explanation for earthquakes became a challenge for scientists of the Enlightenment. The English physician William Stukeley (1687–1765) wrote in his *Philosophy of Earthquakes* that earthquakes were caused by electrostatic discharge between sky and Earth, like lightning.

The most catastrophic earthquake of the eighteenth century occurred in 1755, destroying Lisbon, Portugal, killing about sixty thousand people, and initiating great debate about the cause of earthquakes. The following year the German philosopher Immanuel Kant (1724–1804) proposed chemical causes for earthquakes. He rejected mystical and religious explanations and held that the cause is below our feet.

Important Discoveries

The Englishmen John Winthrop (1606–1676) and John Michell (1724–1793) began to reflect not only on the causes but also the effects of earthquakes. Winthrop, a mathematician and natural philosopher, made the important discovery that earthquakes were waves; this discovery would be revived a hundred years later. In 1760, Michell published a study in which he recognized wavelike motions of the ground. With that he anticipated the perception that would lead to an understanding of the cause of earthquakes.

Another significant step was taken by the Irish engineer Robert Mallet (1810–1881) when he began documenting worldwide earthquake occurrences. He compiled a catalog of six thousand earthquakes from which he was able to draw the most complete earthquake map of the world in 1857. The cause of earthquakes was still unknown, but Mallet's research, which led to the understanding of the

origin of mountains and continents, supplied the basic approach to answering the question. In 1912, the German meteorologist and geophysicist Alfred Wegener (1880–1930) presented his theory of continental drift, which states that parts of the Earth's crust slowly drift atop a liquid core. Wegener hypothesized that there was a single gigantic continent (Pangaea) 200 million years ago.

Causes

Earthquakes are classified as either natural or induced. Natural earthquakes are further classified as tectonic—the most common (more than 90 percent of all earthquakes are tectonic)—volcanic (occurring in conjunction with volcanic activity), and collapse (for example, occurring in regions with caverns). Induced earthquakes are vibrations of the ground caused by human activities, such as construction of dams, mining, and nuclear explosions. For example, filling a reservoir in Koyna, India, induced a catastrophic earthquake in December 1967 that caused 177 deaths.

Most earthquakes are caused by the movement of tectonic plates, as explained by the continental drift theory of Wegener. Tectonic plates are large segments of the Earth's lithosphere (the outer, rigid shell of the Earth that contains the crust, continents, and plates). The Earth's surface consists of nine major plates: six continental plates (the North American, South American, Eurasian, African, Indo-Australian, and Antarctic plates) and three oceanic plates (the Pacific, Nazca, and Cocos plates). Tectonic plates move in relation to each other and along faults over the deeper interior. Faults are fractures in rock along which the two sides have been displaced relative to each other. An example is the well-known San Andreas Fault in California, which separates the Pacific plate (on which San Francisco and Los Angeles lie) from the North American plate.

When lava is upwelling at midoceanic (mid-Pacific, mid-Atlantic) ridges, rock moves slowly on either side of the ridges across the Earth's surface. New plates are constantly created, while other plates must be

absorbed at subduction zones (where the edge of one plate descends below the edge of another).

Earthquakes, volcanoes, mountain building, and subduction zones are generally explained as consequences of steady, large, horizontal surface motions. Most tectonic plates contain both dry land and ocean floor. At present, those plates containing Africa, Antarctica, North America, and South America are growing, whereas the Pacific plate is shrinking. When plates collide, mountain chains such as the Alps and Himalayas arise, accompanied by persistent earthquake activity.

Seismographs and the Richter Scale

Earthquakes are recorded by sensitive instruments called seismographs. Today's seismographs record ground shaking over a band of frequencies and seismic amplitudes. A seismogram (the record created by a seismograph) shows the motions of the Earth's surface caused by seismic waves across time. Earthquakes generate different kinds of seismic waves: P (primary) waves alternately compress and dilate the rock, whereas S (secondary) waves move in a

shear motion, perpendicular to the direction the wave is traveling. From a seismogram, the distance and energy of an earthquake can be determined. At least three seismograms are needed to locate where an earthquake occurred. The place at which rupture commences is the focus, or hypocenter, while the point on the Earth's surface directly above the focus of an earthquake is the epicenter. The distance between the focus and the epicenter is the focal depth of an earthquake.

The amount of energy released by an earthquake is measured and represented by its magnitude. One common type of magnitude measurement is the Richter scale, named after the U.S. seismologist Charles Francis Richter (1900–1985). The Richter scale is logarithmic, meaning the seismic energy of a magnitude 7 earthquake is one thousand times greater than that of a magnitude 5 earthquake.

Earthquake Catastrophes

The following examples from different regions provide vivid examples of the kind of devastation earthquakes can inflict on human populations.

1906: San Francisco, California

The 18 April 1906 San Francisco earthquake, with a magnitude of 7.8, remains one of the most cataclysmic in Californian history. The damaged region extended over 600 square kilometers (about 232 square miles). The earthquake was felt in most of California and parts of western Nevada and southern Oregon. The earthquake caused the longest rupture of a fault that has been observed in the contiguous United States. The displacement of the San Andreas Fault was observed over a distance of 300 kilometers (about 186 miles). The maximum intensity of XI, measured on the Modified Mercalli Intensity Scale ratings of I–XII, was based on geologic effects.

The earthquake and resulting fires took an estimated three thousand lives and caused about \$524 million in property loss. The earthquake damaged buildings and structures in all parts of the city and county of San Francisco. Brick and frame houses of ordinary construction were damaged considerably or completely destroyed, and sewers and water mains were broken, including a pipeline that carried water from San Andreas Lake to San Francisco, interrupting the water supply to the city. This made it impossible to control the fires that ignited soon after the earthquake occurred, and subsequently those fires destroyed a large part of San Francisco. It was not until 1908 that San Francisco was well on the way to recovery.

1995: Hanshin-Awaji; Kobe, Japan

On 17 January 1995, the Great Hanshin-Awaji earthquake with a magnitude of 6.9 occurred directly under the industrialized urban area of Kobe, Japan, a city of about 1.5 million people. The shock occurred at a shallow depth on a fault running from Awaji Island through Kobe. Strong ground shaking lasted for about twenty seconds and caused severe damage over a large area. More than five thousand people were killed; the total cost of damage and destruction exceeded \$100 billion, or

about 2 percent of Japan's gross national product. More than 150,000 buildings were ruined; highways, bridges, railroads, and subways failed; water, sewage, gas, electric power, and telephone systems were extensively damaged.

The city of Kobe—then one of the six largest container cargo ports in the world and Japan's largest—was devastated. Its relative importance as a major hub in Asia declined over the following years, with significant enormous economic consequences. With Japan's having invested heavily in earthquake research, people believed they would be ready for the next earthquake, but their faith was shattered deeply by the Kobe catastrophe.

2003: Bam, Iran

On 26 December 2003, an earthquake occurred below the city of Bam in the southeast of Iran, illustrating again the tragic connection between poor building quality and large numbers of victims. The earthquake had a magnitude of 6.5, and the hypocenter was only 8 kilometers (about 5 miles) below the city. The people of Bam were still sleeping when the earthquake struck. The death toll was estimated at 43,200, with more than 30,000 injured and 100,000 left homeless. The main reason for the large number of fatalities was the generally poor construction quality of buildings, 85 percent of which were damaged. Even though experts had classified the region as a highly exposed zone prior to the earthquake, many of the residences were traditional houses of mud-brick construction, with heavy roofs. Unreinforced masonry holds almost no resistance against the ground motion generated by strong earthquakes.

Preparing for Earthquakes

Increasing population density magnifies the potential damaging effects of earthquakes, especially in urban areas with high seismic activity—for example, San Francisco. For this reason, anti-seismic building codes

We learn geology the morning after the earthquake. • **Ralph Waldo Emerson (1803–1882)**

are important. Appropriate planning and regulation of new buildings and seismic upgrading of existing buildings can safeguard most types of buildings against earthquake shocks. One obstacle to adhering to anti-seismic building codes is high cost; this is true particularly in poorer cities in the developing world, and the effects can be particularly devastating.

Mexico City; Sichuan Province, China; Haiti

The 19 September 1985 Mexico City earthquake, occurred 200 kilometers (about 124 miles) from Mexico City, but the shaking of loose sediments in the city was much stronger than at the epicenter. Nearly ten thousand people died, and the city was heavily damaged as poorly constructed buildings collapsed. The earthquake destroyed as many as 100,000 housing units and countless public buildings.

Hundreds of millions of people live in buildings that would collapse in a strong earthquake, as happened in the mountainous Sichuan Province of China in 2008, when as many as 90,000 people were killed or remain missing, with another 374,000 injured and at least 15 million displaced.

On the afternoon of 12 January 2010, an earthquake with a magnitude of 7.0 devastated parts of Haiti, a nation on the island of Hispaniola in the Caribbean; it was the strongest in the region in over two hundred years. The earthquake occurred at a fault that runs right through Haiti and is situated along the boundary between the Caribbean and North American plates; the epicenter was just 16 kilometers (10 miles) south of the capital, Port-au-Prince, whose population at the time was over 2 million. Aftershocks continued for days, including one a week later registering a magnitude of 5.9. As of late January 2010 the projected death toll ranged from 70,000 to 200,000. The severity of the earthquake

was exacerbated by two factors: the depth of the quake was shallow, meaning that energy released was closer to the Earth's surface and less able to be absorbed by the Earth's crust; and nearly all of the buildings in Haiti were substandard construction, many cinderblock and mortar.

It is anticipated that, in the future, more catastrophes with high death tolls will occur. Owing to the rapid growth of many developing-world metropolises in highly exposed regions, such scenarios are distinctly more probable, despite the possibilities provided by modern earthquake engineering.

As of 2010, the time, location, and magnitude of earthquakes cannot be accurately predicted. Damage and casualties can be minimized, however, if builders adhere to building codes based on the seismic hazards particular to their areas.

Ecological Imperialism

Ecological imperialism is the process by which colonizers carried the plants, animals, and diseases of their homeland to new lands, albeit sometimes unintentionally. Changing a new environment to more closely resemble a familiar one was often critical to the establishment and success of the imperialists, most prominently Europeans in the Americas, Africa, and Oceania.

Imperialism is usually considered to be a political and sometimes an economic or religious phenomenon. But it also has an ecological side: imperialists have intentionally, more often unintentionally, and always inevitably carried with them plants, animals, and microlife from their lands of origin to their new lands. Where imperialists have been successful not simply in conquest but also in settlement, they have done so with the indispensable assistance of the life forms they brought with them. The most successful imperialists have been those who have, as much by chance as intention, changed the flora and fauna, macro and micro, of their new environments to be much like their old environments.

Immigrant life forms often have done poorly in their new homes: for instance, attempts to permanently establish the European nightingale in North America have never succeeded. But these immigrants, moving into environments where organisms were not preadapted to prey on or effectively resist them, have often done well indeed.

Examples of Ecological Imperialism

Ecological imperialism is as old as human migration. For example, the ancestors of the Australian

aborigines arrived in Australia from the Malay Archipelago fifty or so thousand years ago and some millennia afterward imported their dog, the dingo—the continent's first domesticated animal—which figured importantly in their success there.

The best examples pertain to European expansion because the Europeans were the first to habitually cross oceans, that is to say, to travel between continents with sharply contrasting biotas (flora and fauna). The human invaders' attendant organisms spearheaded alterations in local ecosystems essential for the biological and economic success of the humans. This can be considered under three headings: crops, animals, and diseases.

Crops

Europeans learned to eat the foods of America and Oceania (lands of the Pacific Ocean) but generally preferred their own food, planting wheat, barley, rice, turnips, peas, bananas, and so forth in their colonies wherever they would grow and as soon as was practical after arrival. These crops were often particularly important in enabling the imperialists to live in numbers in areas where indigenous crops did not grow well. A good example of a successful European crop is wheat, which prospers where Native American cereals do not and provided the nutritional and economic foundation for large populations in the temperate-zone grasslands of North and South America and Australia.

Animals

European imperialists were most successful where there were few domesticated animals prior to their

Roundup on the Sherman Ranch, Geneseo, Kansas. The horses and cattle were brought to North America from Europe. New York Public Library.

arrival. In America imported pigs fed on a great variety of locally available substances propagated wildly, and pigs generously provided proteins and fats for the imperialists. Imported cattle turned what humans cannot eat—grasses and forbs (nongrass herbs)—into what they can eat—meat and milk—and were running in vast feral herds in northern Mexico and Argentina within a century or so of their arrival. Old World sheep also thrived in many of the colonies, and their numbers exploded in Australia and New Zealand. Where these and like quadrupeds—goats, for instance—did well, so did the Europeans.

Horses were slower than most imported quadrupeds to have population explosions, but they did so in time. They made supermen of the invaders in battle with native foot soldiers, most of whom had never seen such large animals before and none of whom had ever seen an animal carry a human and obey human will.

The biological revolutions underlying these successes were much more complicated than simply bringing crops and animals ashore. Whole ecosystems or at least several of their components had to be imported, too. For example, in the thirteen colonies and then the early states of the United

States one of the problems of establishing large herds of domesticated animals from Europe was the fact that native grasses and forbs, products of millennia free from the tread and teeth of domesticated herds, did not tolerate heavy grazing pressure well. The importation and then often-rapid expansion of European forage plants—for instance, white clover and what Americans inaccurately call Kentucky bluegrass—unrolled a carpet of food for immigrant quadrupeds. Much the same thing happened in the humid zones of Argentina, Australia, and Argentina.

Diseases

In the first stage of European imperialism in the Americas and Oceania the triumph of the invaders over the natives seemed unlikely. The newcomers were always outnumbered. They were isolated by whole oceans from their home bases and were inexperienced in even how to survive in the new and alien environments. They were in need of powerful allies, such as the animals cited earlier and the germs they and their animals brought in their blood and breath. The Old World invaders' advantage was that their microorganic evolution and human history were different than those of the natives of the New World.

Heavy populations dependent on agriculture appeared earlier in the Old World than elsewhere, most significantly in crowded and filthy cities, providing the pathogens with food, habitat, and opportunity for transmission. Heavy populations of domesticated animals first appeared there likewise, providing more habitats for pathogens and opportunities for jumping from one species to another, including humans. The possibilities for epidemiological disasters were multiplied by the penchant of Old World peoples for long-range commerce.

When European imperialists crossed the oceans they brought with them infections unknown to American and Oceanic peoples, whose general density of population was low or relatively new, as were their cities. Large herds of domesticated animals were rare or

nonexistent, and the tempo of long-range commerce was relatively low. Thus native peoples were unfamiliar with such infections as smallpox, measles, typhus, influenza, yellow fever, and malaria.

The most important or at least most spectacular of these infections in ecological imperialism was smallpox. It first arrived in the West Indies at the end of 1518, spread rapidly through the Greater Antilles and then on to Mexico, where Hernán Cortes and his conquistadors had just been driven out of the Aztec capital. All or nearly all of the Spaniards had already had the disease on the other side of the Atlantic and were immune. The peoples of Mexico were universally susceptible and died in droves.

Similar sequences of events occurred elsewhere in the Americas and Oceania. For example, the way was cleared for the Pilgrims who arrived in Plymouth, Massachusetts, in 1620 by some sort of devastating epidemic in 1616. For another example, smallpox raced through the aborigines of New South Wales in 1789 soon after the arrival of the Botany Bay colonists.

Failure of Ecological Imperialism

Where the Europeans' attendant organisms, macro and micro, triumphed, as in temperate zone regions of America and the southwest Pacific, the Europeans took over demographically. Where the triumph was mixed, as in tropical America and South Africa, the Europeans conquered militarily but not demographically. Where the attendant organisms had only minor effect, as in tropical Africa and Asia, the Europeans failed to found

colonies of settlement and were ejected in the twentieth century.

Ecology, Cultural

The anthropological field of cultural ecology asserts that societies develop on paths related to their environmental circumstances: culture is often a mode of adaptation. Since the mid-twentieth century when it emerged, cultural ecology has developed varying foci and assumed several different varieties. Whether nature influences culture, or culture effects the environment, is a debatable topic among cultural anthropologists.

Cultural ecology in a wide sense denotes a concern with the relationship between human culture and the natural environment, and in a narrow sense a particular perspective on this relationship that was first developed by anthropologists such as Julian Steward (1902–1972) and Leslie White (1900–1975) in the late 1940s and the 1950s. Steward and White were both critical of the historical particularism that dominated American anthropology in the early decades of the twentieth century through the influence of Franz Boas (1858–1942), Alfred Kroeber (1876–1960), and their students, who rejected any attempt to explain cultural phenomena by reference to noncultural factors such as evolution or environment. Although the differences between Steward and White were considerable, they converged in the ambition to revive an evolutionist and comparative perspective on culture, and in seeking explanations of cultural forms in technological and environmental factors. Both had a materialist orientation, influenced by Marxism, and tended to regard the social and ideational aspects of culture as accommodations to its technoenvironmental aspects.

Steward emphasized what he called the culture core, that is, those features of a society most closely

associated with subsistence, as an adaptation to specific environmental conditions. He then classified societies with similar cultural cores into categories that he called culture types. Finally, he sorted these culture types into a series of stages based on their complexity or level of sociocultural integration, which later provided the foundation for his student Elman Service's (1915–1996) influential evolutionary sequence: bands, tribes, chiefdoms, and states. Steward offered a theory of multilineal evolution, distinct from nineteenth-century unilinear evolutionism. By this he meant that societies could develop along different paths depending on their environmental circumstances.

White also argued for an evolutionary perspective on culture as a mode of adaptation, but focused on technological advances in the harnessing of energy as the standard by which to measure evolutionary progress. Whereas Steward's evolutionism was specific and relativistic, White's was thus general and universalistic.

Steward's and White's cultural ecologies prepared the ground for the emergence, in the 1960s and 1970s, of an ecological anthropology influenced by cybernetics, general systems theory, and the rapidly developing science of ecology. Much of the research conducted under this label has been concerned with the relation between local populations and their natural habitats, interpreted in terms of human adaptation to an ecological niche and the maintenance of sustainable energy flows in local ecosystems. Most faithful to the Marxist roots was Marvin Harris's (1927–2001) cultural materialism, a perspective that viewed seemingly arbitrary cultural phenomena (e.g., the sacredness of India's cattle) as reflections of an underlying material rationality (in this case, the productive importance of

Anthropologist Julian Steward, right, sits next to a man thought to be Chief Louis Billy Prince, a Carrier Indian who was a source for Steward's research (c. 1940). The National Anthropological Archives, Smithsonian Institution.

cattle in India), thus representing an extreme version of cultural ecology's ambition to explain culture by reference to nature. A more sophisticated version was Roy Rappaport's (1926–1997) account of ritual pig slaughter in highland New Guinea as a cybernetic feedback mechanism that maintained ecological equilibrium and cultural stability. In synthesizing influences from materialist cultural ecology, on one hand, and the cybernetics and communication theory informing Gregory Bateson's (1904–1980) ecology of mind, on the other, Rappaport pioneered a more holistic ecological anthropology that sought to address both material and ideational aspects of human–environmental relations. Another school of ecological anthropology, represented by neoevolutionists such as Morton Fried (1923–1986), Elman Service, and Kent Flannery (b. 1934), maintained a focus on tracing long-term processes of sociocultural development to explain the origins of increasing social complexity.

Critiques

A number of criticisms have been directed at these various versions of cultural ecology, the most general of which are their inclination toward environmental determinism and their neofunctionalist assumptions of adaptation. It has often been observed that to demonstrate the ecological consequences of a cultural

institution is not to explain its existence. Marxist critics also point out that an emphasis on the ecological functions of culture neglects the crucial role of conflict, power, and contradiction in sociocultural processes. White's Marxist-inspired technological optimism, on the other hand, is difficult to reconcile with world developments since the 1950s. His law of cultural evolution, which ambiguously refers to both the *amount* of energy harnessed per capita and the *efficiency* of energy use, did not reckon with the possibility that quantity and efficiency (what his students Marshall Sahlins and Elman Service later distinguished as thermodynamic *achievement* versus thermodynamic *efficiency*) may in fact be inversely related in world history. The simpler and less energy-intensive a society is, the more efficient its energy use is likely to be. Nor did White consider the possibility that the expanded levels of thermodynamic achievement (technological development) that he visualized as the foundation of an egalitarian future world might be dependent on an unequal exchange of energy and other resources in global society. In their inclination to focus on local populations and ecosystems, and on technology as a local phenomenon, cultural ecology and subsequent proponents of ecological anthropology have generally underestimated the role of global or even regional systems and processes in shaping local economy and culture. The recently expanding field of

The Law of Cultural Development: culture advances as the amount of energy harnessed per capita per year increases, or as the efficiency or economy of the means of controlling energy is increased, or both. • **Leslie White (1900–1975)**

Anthropologist Leslie A. White (c. 1960s). Bentley Historical Library, University of Michigan.

political ecology, however, is a promising antidote to such parochialism and political naivety. In addition to exploring applied environmental issues such as sustainable development, environmental justice, ecological economics, and the tragedy of the commons (i.e., the overuse of common property resources by people pursuing their individual interests), political ecology has generated new theoretical frameworks for understanding how environmental issues, power, and inequality are intermeshed.

In recent years, the label *environmental anthropology* has been used in a general sense for anthropological studies of human–environmental relations, including those whose concerns transcend the questions traditionally asked by cultural ecology and ecological anthropology. This more inclusive label

should arguably be extended to the ethnoecology pioneered in the 1950s by the cognitive anthropologist Harold Conklin (b. 1926). A subfield of ethnoscience, this method uses linguistic analysis of native (emic) categories to map a group’s own view or knowledge of their natural environment.

Environmental anthropology would also include the symbolic ecology launched in the 1990s by Philippe Descola (b. 1949), building on the structuralist perspectives of Claude Lévi-Strauss (1908–2009). Apparently sharing Lévi-Strauss’s position that nature and culture are universal cognitive categories, Descola has redefined animism and totemism as mirror images of each other, metaphorically transferring meanings from society to nature and from nature to society, respectively. Symbolic ecology shares with ethnoecology a focus on the cultural construction of the environment, rather than on how the environment shapes culture. Finally, also in the 1990s, Tim Ingold (b. 1948) has developed an approach to human–environmental relations, inspired by, for example, phenomenology, ecological psychology, and Gregory Bateson, that he calls relational-ecological-developmental. Ingold rejects the universality of the distinction between nature and culture by showing that such categories are generally alien to hunter-gatherers. He also rejects the view that knowledge of the environment is either a representation or a construction of reality, in favor of Bateson’s view that knowledge is a relation that shapes both the knower and the known, both subject and object. Ingold challenges all notions of cultural or biological inheritance, arguing instead that humans are constituted (as indissolubly persons *and* organisms) through practical enskilment and engagement in specific environments. As for Bateson and Rappaport, the thrust of this effort is to transcend the conventional dualism in Western thought that separates material and ideational aspects of human–environmental relations.

Economic Cycles

From the beginning of the widespread use of money in China, circa the year 1000, to the trade and budget deficits of the twenty-first century, economic cycles have plagued most of the world. Economists have argued endlessly and inconclusively about exactly what caused these booms and busts, and which governmental policies might counteract their troubling effect on human lives.

In recent centuries, economic cycles—years of boom leading up to a sudden bust followed by a period of hard times—began to prevail in most of the world. Why that irregular rhythm exists remains a matter of debate among economists and politicians. In the deeper past other disasters—crop failure, epidemics, and the ravages of war—often afflicted our ancestors, and years of plenty and years of hunger affected almost everybody in course of a lifetime. But the modern pattern of boom and bust arose only when the use of money became widespread and introduced a powerful new variable into human behavior.

From Crops to Coins

The widespread use of money first occurred in China about the year 1000, after the government decided to collect taxes from peasants in coin instead of demanding a share of the harvest, as they had before. Paying in coin required millions of ordinary persons to find something to sell, and the effect at first was to launch a sustained boom since buying and selling among scores of millions and across hundreds of miles along China's two principal rivers rewarded efficiency and increased specialization of production.

Wealth multiplied accordingly, and Chinese officials soon resorted to printing paper money to supplement coinage and make large-scale payments easy. Surviving records do not show whether anything like modern patterns of boom and bust developed in China, but we do know that when Mongol conquerors invaded and eventually founded the Yuan dynasty (1279–1368), paper currency ceased to circulate, since prolonged warfare provoked reckless printing of paper money and made it worthless. That bought on so big a bust that the Chinese relied entirely on coins for centuries thereafter.

As far as historians can tell, ancient Greece and Rome never experienced modern forms of boom and bust, though when Alexander of Macedon (Alexander the Great, 356–323 BCE) captured the Persian treasury and began to spend its contents lavishly, he provoked a boom of sorts. It was prolonged by his Greek and Macedonian soldiers who founded scores of cities throughout the empire and put a vastly increased amount of money into circulation. During the early Roman Empire (30 BCE to 180 CE) money payments sustained the circulation of wine, olive oil, and grain throughout the empire, but neither boom nor bust can be clearly detected before epidemics and invasion impoverished everyone. Thereafter, widespread return to local self-sufficiency made money marginal in most of Europe again during the early Middle Ages.

After about 1000, however, long-distance trade began to flourish anew in Europe and money again financed it. That provoked a long-term boom as warm weather brought improved harvests, population grew, and extensive new fields were carved from the forests. Money circulated more and more freely, and the first unmistakable bust came in 1343–1344, when Florentine banks went bankrupt

after King Edward III of England repudiated his debts, and bank-financed export of raw wool from England to Flanders and Italy suffered interruption. Sheep farmers in England, spinners and weavers in Flanders and Italy, and the merchants who distributed woolen cloth throughout Europe and the Mediterranean coastlands all suffered severe losses of income.

Plague and Tulip Mania

Before full recovery, a far greater disaster came in 1346 when the Black Death (almost surely bubonic plague) arrived in the Crimea and in the next three years spread almost everywhere across Europe, killing about one third of the entire population. The enormity of that disaster was never forgotten and made the financial crisis that had temporarily paralyzed the wool trade seem trivial. In spite of efforts at quarantine, plague continued to break out in Europe at irregular intervals for the next few centuries, and population continued to decline until about 1450. Whenever plague raged all ordinary business was suspended and recovery often came slowly. But alternating boom and bust, if it existed apart from epidemics and warfare, was not conspicuous until the seventeenth century, by which time private financial deals had attained a greater scale than before.

The so-called tulip mania in Holland was an unusually bizarre example. Tulips reached Europe from Turkey only in 1550, and their vivid and varied colors attracted much attention from the start. Prices for rare varieties began to rise in northwestern Europe. The boom reached its climax in Holland between 1633 and 1637 when thousands of persons invested in bulbs, hoping to sell them almost immediately at a higher price. Sometimes an especially precious bulb remained safely in the ground and was sold and resold at higher and higher prices until the bubble broke early in 1637. Many Dutch families suffered financial disaster because they had tried to get rich quickly by mortgaging homes and other valuables to enter the tulip market. Consequently the bust affected the whole

economy. Foreigners had also rushed to buy, so the bust extended more faintly to other parts of Europe.

The tulip mania differed from earlier boom and bust cycles by depending on widespread hope and the expectation of making a fortune almost overnight by speculating on the rising price of tulip bulbs—an object no one needed for anything but luxury display. Initial instances of attaining sudden wealth provoked a crowd reaction as thousands rushed into the market to get their share of the bonanza, pushing prices to ridiculous and unsustainable extremes. At the time, the Dutch were busy building an empire in the Indian Ocean, the Caribbean, and Brazil; Dutch trade flourished and the country's general prosperity may have been what allowed so many to invest so foolishly in tulips.

But this was not the only time that similar crowd behavior, seeking sudden monetary wealth, provoked comparable booms and busts. One of the most notable of these centered in France when a Scottish economic theorist and adventurer named John Law persuaded the government in 1716 to allow him to found a bank that would sell its stock to the public, have the right to issue paper money, and use its resources to develop the potential wealth of the territory of Louisiana in the Mississippi valley of North America. Law's bank prospered for a while when a rush to invest raised the price of its stock, as well as stock in several subordinated companies, very high. One of them took over tax collection in France itself and promised to pay off the entire royal debt. But there were doubters from the start, and when enough investors lost faith in Law's "system" for making money, the whole scheme suddenly collapsed in 1720. Law fled to Venice, leaving a host of angry and impoverished private investors, together with burdensome and disordered government debts, behind.

In 1718 a similar but less massive boom got underway in England when the South Sea Company, chartered to sell African slaves to the Spanish Empire in America, took a leaf from Law's book and persuaded Parliament to let it take over the national debt. For the next two years the two booms ran parallel. The price of South Sea Company shares multiplied almost

800 percent in the first months of 1720; in France shares in Law's companies rose by twice as much, and then both collapsed in just a few days. Subsequent investigation in England showed that government ministers had been bribed. They and the company's directors were disgraced, but the company itself survived until 1853, long after Great Britain had abolished the slave trade. Unlike the situation in France, government debt, managed by the Bank of England since 1694, was not much disturbed.

Industrial Revolution—Wars and Peace

Gains and losses from short-lived, get-rich schemes like these remained comparatively superficial as long as most of the population remained on the land, where they prospered or suffered from variations in the harvest but were little affected by financial shenanigans in the cities. Wars and the expansion of industry in parts of Europe changed, so that by 1815 a crisis of confidence among bankers, whose loans were needed to keep both factories and governments in operation, became capable of diminishing a whole nation's welfare.

This vulnerability started with the so-called Industrial Revolution in Great Britain. It was achieved between 1750 and 1815 very largely through a series of booms and busts driven by government borrowing for war expenditures in the periods from 1754 to 1763, 1776 to 1783, and 1792 to 1815. Borrowed money equipped the country's army and navy with vast quantities of cloth, guns, cannon, and other supplies. Accordingly, factories, forges, and mines rapidly expanded their capacity to supply the necessary materials, and faced hard times whenever government orders were suddenly cut back in peacetime. But the net effect of these long wars was to expand industrial production and employment, as first water power and then steam engines put new machines into motion, inaugurating cheap mass production of cloth and other commodities.

Warfare diminished after 1815, and peacetime rhythms of boom and bust began to manifest themselves

more insistently. Government expenditures ceased to dominate the business cycle; instead privately financed new technologies—railroads above all—took primacy. In 1825, the first steam-powered railroad demonstrated how dramatically even rickety rails and a tiny steam engine could lower overland transport costs. Almost at once private companies and then governments began to build railroads around the world. Initial costs for shaping a smooth and stable road bed were high and required large loans. Moreover, in the United States and Canada transcontinental railroad construction soon outstripped frontiers of settlement. This in turn provoked intensive land speculation wherever people thought a new town might arise along the track.

As a result, some profited and others lost from speculative investments, and alternating booms and busts became frequent. They often spread from country to country wherever railroading, land speculation, and related new technologies—steamships, telegraphs, Bessemer steel furnaces, and literally thousands of other novelties—kept on altering everyday lives.

In the 1850s a Frenchman named Clement Juglar was the first to suggest that a business cycle of eight to ten years had become normal. An unusually severe depression occurred in 1873, followed by another in 1893, and World War I (1914–1918) suddenly transformed peacetime economic behavior more drastically than ever before. In the light of this experience, in the 1920s a Russian economist, Nikolai Kondratieff, proposed a fifty-year cycle of expansion and contraction behind and underlying the shorter, more superficial ups and downs of market prices.

Since then economists have argued endlessly and inconclusively about exactly what caused booms and busts, and which governmental policies might counteract their troubling effect on human lives. After World War I, booms and busts became more damaging than before as farming ceased to employ the majority of the total population in more and more countries, and variations in harvest yields lost most of their former importance.

In most of the world, World War I was followed by a short depression, then a boom that lasted

until 1929; then came what is often called the Great Depression of 1929 to 1938. But Communists who had come to power in Russia in 1917 experienced a different cycle—destructive civil war, a brief return to small-scale private buying and selling, then forcible collectivization of agriculture and ambitious five-year plans for industrial construction. Resulting industrial expansion coincided with the Great Depression and seemed to show that Communists had solved the problem of boom and bust by resorting to official command and deliberate planning.

The onset of World War II (1939–1945) abruptly ended the Great Depression, and brought something resembling Communist-style command economies to all the principal belligerents. But in non-Communist countries, postwar return to free markets worked better than ever when efforts by central bankers to move interest rates up and down seemed for a while to have softened the impact of boom and bust, while the Russians and a new Communist regime in China struggled to repair wartime damages. Until about 1970, the Cold War between Communist countries and the self-styled “free world” was in stalemate by a balance of atomic terror. But by the 1990s a long-sustained economic boom, punctuated only by slender and short-lived busts in America and western Europe, began to outstrip the Russia’s achievements, where wasteful use of manpower and other resources hampered the command economy.

Chinese Communists forestalled comparable difficulties in 1981 by relaxing state controls and inviting peasants and other entrepreneurs to seek private profit by relying on market prices for whatever they produced. Thereupon, China launched itself on a sustained boom and soon far outstripped the rate of growth in the rest of the world. Russian Communists tried to follow suit in 1987 and 1988, but, unlike the Chinese, they provoked widespread impoverishment as inefficient factories shut down and political discontents boiled to the surface. The upshot was a surprisingly peaceable disruption of the Soviet Union in 1991. A diminished Russian republic emerged, which is still in pursuit of a satisfactory balance

between political and private management of economic affairs.

An Uncertain Future

A strange partnership spanned the Pacific as the Chinese boom became manifest. Americans started to buy cheap Chinese goods and outsourced manufacture to China on an unprecedented scale, while the Chinese government bought billions of dollars of U.S. bonds to keep their boom, and American prosperity, going. American national prosperity itself began to take on a feverish quality. Government expenses for war in Iraq and Afghanistan increased while tax rates for the wealthy were reduced, so budget deficits ballooned at the same time that cheap goods from China increased the trade deficit while also restraining some prices. But not all prices. When American bankers began to sell mortgages to marginal borrowers and then bundled thousands of them into a new kind of security called “collateralized mortgage obligations,” the price of housing rose even faster than the stock market. Irresponsible boom set in when more and more home buyers signed mortgages hoping to get rich quick by selling again at a higher price, just like those who had bought tulip bulbs in Holland 375 years before.

Thus the American and the global financial system headed for another bust. It arrived in August 2007, and has yet to be resolved in 2009. Initial efforts by the U.S. government to save banks and insurance companies from bankruptcy by loaning them billions of dollars have not forestalled rapidly mounting unemployment, and the world’s economic future remains profoundly uncertain. Even the Chinese feel threatened. Moreover, behind the financial bust loom problems of diminishing oil supplies, mounting environmental pollution, global warming, and other foreseeable difficulties. Most urgent of all, no one knows how, when, or even if, financial recovery will come.

Economic Growth

The term *economic growth* is used to indicate the increase of gross domestic or national product of a society; it can be divided into two categories. *Extensive growth* refers to increases that result from mobilizing more of the basic factors of production: land, labor, and capital. *Intensive growth* refers to growth that results from using the same factors more efficiently.

Economic growth is an increase in the total value of goods and services produced by a given society. There is little common agreement, however, on how best to measure this value. Many distortions are possible even in societies where most goods and services are provided by specialists and exchanged for money—so that prices provide some standard of measure of the relative value people assign, for instance, to a sack of rice, an hour of child care, an automobile, or a concert ticket. Measuring economic growth is still more difficult where economic activity is carried on outside the market, and thus not given a price that makes it comparable to other products. (For example, if hired cooks are paid enough each hour to buy five square meters of cloth, then we know something about how to add cooking and cloth making together in an index of total value produced; but if all families cook for themselves, it becomes much harder to know how to do that addition.)

Definitions

Despite these difficulties, it is widely agreed in principle that one can arrive at a total value for a society's economic production, and that an increase in this number—economic growth—indicates an increase

in material abundance in that society. Therefore, economic growth can have a significant influence on human welfare, though it does not automatically indicate material betterment; growth that is mostly directed toward building weapons, for instance, or growth that is so unevenly distributed that the number of very poor people is increasing would not do much to improve overall material welfare. Still, there is enough correspondence between economic growth and the capacity to meet material goals, whatever they may be, that in the twentieth century, measures of economic growth probably became the most widely used indicator for trends in aggregate human material welfare, both in the present and the past. Even those who are very skeptical of equating output with welfare usually agree that *something* important about a society is being measured when we measure the level and rate of change of its economic output.

Economic growth is usually further divided into extensive and intensive economic growth. This distinction is clear in theory but messy in practice. *Extensive growth* refers to an increase in economic production that results from mobilizing more of the three basic factors of production: land, labor, and capital. If a farmer who used to work 50 days a year sowing 20 pounds of seed on 10 acres of land begins to work 100 days a year and sow 40 pounds of seed on 20 acres, thereby doubling his crop, this is pure extensive growth. *Intensive growth*, on the other hand, refers to growth that does not require more factor inputs, but results from using these inputs more efficiently; this could result from new technology, a more efficient social organization of production, or increases in knowledge that make workers more efficient. If

Quiringh Gerritsz van Brekelenkam, *The Tailor's Workshop* (1661). Oil on canvas. During the “industrious” revolution, ordinary people worked more hours for the market—not just to get essentials but to acquire luxuries.

two people who used to each need a week to build a shelter start working together so they can build three shelters in that time—increasing their output without using any more materials or labor time—that is intensive growth.

Extensive growth comes with obvious costs and is presumably finite; on the other hand it is extremely common in world history, since it is an option open to any society with unused land, free labor hours, and so on. By contrast intensive growth can be nearly free, (though not entirely so, since considerable resources for research and development might be invested in figuring out how to do things better); in principle it is also infinite, since it requires no additional material resources. On the other hand, it is not obvious that every society at every time can experience very much

intensive growth. Consequently economic historians have devoted considerable attention to trying to identify which times and places have seen important bursts or sustained periods of intensive growth, and social and economic theorists have devoted just as much attention to trying to extract from these cases a general set of conditions conducive to intensive growth.

In practice intensive and extensive growth often occur together. If a new kind of plow makes it possible to grow grain on land that would not previously support it, the innovation represents intensive growth; but the extra labor, seed, tools, and so on needed to maximize the benefit of the innovation represents an extensive component. Many technical or social changes also result in a switch from using one kind of

input to another (from horses and hay to cars and oil, or from 50 hours of labor and a very cheap spinning wheel to a few minutes of labor and a huge machine); this may cause large changes in the relative value of these inputs. An hour of a handloom weaver's labor bought three or four days worth of food in parts of eighteenth-century China; today that labor is worth very little. It can be very hard, therefore, to decide how much of a given episode of growth to assign to the intensive or extensive category. Still any understanding of the changing material life of humans requires trying to sort this out.

Three Eras of Growth

Though it is hard to prove, most growth prior to the nineteenth century is regarded as having been extensive, resulting from more people expending labor on more of the Earth and its products. On the other hand, most growth in the nineteenth and twentieth centuries has been intensive. Systematic science has increased the speed with which new ways of doing things are discovered and disseminated, and supposedly more-efficient forms of economic organization have diffused around the world under the increased competitive pressure wrought by improved transportation and increased trade.

As a very rough approximation, this is probably correct, but any full story would be much more complicated. A fuller analysis shows that three critical eras account for most of the economic growth in human history, and that the combination of intensive and extensive growth is different in each case.

Neolithic Revolution

Through the millennia during which people were hunter-gatherers, there were many examples of unrecorded intensive growth: gradual improvements in hunting techniques, expanding knowledge of what plants were edible and how to find them, and so on. Studies indicate, however, that these did not lead to substantial increases in per-capita income, because people who were often on the move had no incentive to accumulate possessions, unless these possessions

could walk, and the only animal that seems to have been widely domesticated well in advance of the emergence of settled farming was the dog (used in hunting). Thus whatever economic growth there was in the long period from the first emergence of humans until about ten thousand years ago was mostly reflected in population growth, as people spread out of Africa and gradually covered all the habitable portions of the Earth, probably by roughly thirty thousand years ago.

The efficiency gains from learning to do things better also enabled particular bands of humans to feed themselves with fewer hours of labor—an important improvement in human welfare, but one that does not show up as economic growth. Studies of modern hunter-gatherers suggest that they eat reasonably well with a work week of fewer than thirty hours per adult. Thousands of years ago, before agricultural and industrial societies pushed them onto marginal lands, these people could probably feed themselves with less work.

The first concentrated burst of intensive and extensive growth, then, was probably the so-called Neolithic revolution: our name for a cluster of innovations that includes settled farming, the domestication of animals, and the construction of permanent settlements. Controversy continues about how and why this process occurred—and it seems to have occurred independently in at least six places in the world. In the short run, these developments did not make life easier for individuals. Early farmers lived no longer than their nomadic ancestors, and they almost certainly worked much harder. Skeletal remains suggest they were shorter (which usually means less well nourished) and suffered more injuries of various sorts. They certainly suffered more from contagious diseases, as people occupied large-enough settlements for various diseases to become endemic, and as they stayed for long periods in proximity to their own waste, and to animals that hosted diseases.

On the other hand, settled societies could achieve far-higher population densities, because each acre of land in settled areas was now devoted only to plants

useful to humans, and human activity—such as weeding and watering—increased the yields of these favored species. Staying in one place also made it easier for women to have more children, since children did not need to be carried as much as they did in migratory bands. For the same reason, settling down also facilitated the accumulation of material possessions. The overall result was substantial economic growth: more people and more output per person resulted from both an increase in inputs (more laborers, each working more hours on average) and eventually from greater efficiency. Permanent settlement also facilitated the storage of food and thus the feeding of people who themselves might not produce food. This made greater occupational specialization possible, which in turn facilitated the discovery and diffusion of knowledge, manifested in the rise of advanced construction, metalworking, cloth making, and many other skills.

Thus intensive growth encouraged extensive growth, and vice versa. Within a few thousand years of the first agricultural settlements there grew cities, governments, and writing—as well as far greater human inequality, which both reflected the accumulation of goods and served as a spur to further accumulation. While no good numbers for economic growth exist for this period, estimates of human energy consumption are a useful (though very inexact) proxy. A very rough estimate is that in the era of hunter-gatherers, perhaps 6 million humans each directly or indirectly used about 5,000 calories per day, for a total of 30 billion calories per day worldwide; by 5,000 years ago, perhaps 50 million people burned an average of 12,000 calories per day, for a total of 600 billion calories. Including improvements in the efficiency with which energy inputs were turned into output of human goods, economic growth in this period exceeds 2,000 percent; but since this was achieved over perhaps 5,000 years, the annual growth rate was still minuscule.

From perhaps 5,000 years ago to roughly 500 years ago, economic growth was primarily a matter of slow extensive growth—mostly clearing forest or jungle to create more farmland and accompanying

population growth. The global population reached perhaps 500 million by 1500 CE, for a growth rate of less than 0.1 percent per year. Technical and institutional innovations also continued, but slowly. Not only was the rate of invention slow compared to the last century or two, but the rate at which new techniques spread across the world was very slow, due to limited communications. Iron plows, paper, and other very useful innovations took centuries to spread from China, where they were invented, to the other end of Eurasia, not to mention to the Americas or Australia; the manufacture of paper, for instance, is noted in China in about 100 CE but not in Europe until after 1200. Productivity-enhancing institutional innovations, such as the growth of markets in land and labor, were often even slower to spread, since they threatened the vested interests of those who controlled these resources by force. It was also probably common for useful innovations to be lost periodically, since small societies were easily disrupted and much of their knowledge was never written down.

Innovations occasionally came in clusters, as in Song China (960–1279), when breakthroughs in water control, rice growing, silk reeling and weaving, navigation, and time keeping were all invented in a relatively short time. Whether coincidentally or otherwise, Song China also saw a marked institutional shift away from self-reliant estates that made heavy use of compulsory labor; instead people at all levels of society began to rely more on markets and to specialize in a few goods or services they could sell in exchange for others. The growth of markets was certainly not new or unique to Song China, but that appears to be where it first reached the critical level at which the process became self-sustaining. This pattern of commercialization spread outward from China and a few other centers, though the degree to which it prevailed in any particular society remains controversial among historians.

Migrations and conquests could also suddenly spread a great many innovations all at once. Muslim conquerors spread rice, sugar, oranges, cotton, and other crops westward, having earlier obtained these

London, Liverpool Street Station (c. 1910). During the industrial age, railways enabled goods, materials, and people to travel great distances in a short time, spurring economic growth.

plants via trade with India; they also played a very important role in spreading Persian irrigation techniques and medical techniques derived from India, the ancient Mediterranean, and the Arab world. But more often, centuries separated major inventions, and they spread rather slowly. By Roman times, agricultural yields in parts of Italy had reached levels that would not be exceeded until 1800 (though the number of places in Europe achieving those yields increased as efficient practices slowly spread). The same was true of the most productive farms in eastern China, which by 1200 (at the latest) had reached yields not reliably exceeded until well into the twentieth century. Even within the small space of England, the top wheat yields on medieval manors set a standard that did not become common until roughly 1800. Every piece of land is subtly different from others in soil chemistry, drainage, sun and shade, and so on, and before the advent of modern chemistry, adopting what worked on somebody else's farm was a laborious trial-and-error exercise for even the best-informed and most diligent farmers.

By the fifteenth century, however, a new phase of growth was beginning to appear in various parts of the world, composed of three loosely related elements: more rapid population growth and land clearance (extensive growth); an "industrious revolution," in which people began to work longer and harder (extensive growth) but also more efficiently (intensive growth); and technological change, which increased

slowly before accelerating sharply in the Industrial Revolution of the nineteenth century.

The Industrious Revolution

Populations across Eurasia recovered from the fourteenth-century plague during the following century, eventually reaching previous peak levels; but this time, they didn't stop: for reasons that are unclear, world population had reached almost 1 billion by 1800, roughly twice its previous peak. Land under cultivation also increased, though not as fast as population: frontiers were pushed back in eastern Europe, southwest China, the interior of India, the Americas, and many other places. In many cases, the advance of cultivation went along with small but significant technical improvements: new seeds better suited to harsh conditions, better water pumps for irrigation, improved knowledge of crop rotation. At the same time, yields per acre rose, though often painfully slowly. For instance, the practice of double-cropping—squeezing in a second crop on the same piece of land in one year—became much more common, especially in east and south Asia. This helped support more people, but the second crop often yielded less output for each day of work than the primary crop. In nonagricultural occupations as well, output rose, but hours worked seem to have risen even faster.

In Europe, where the best data exists, the number of hours of work required to earn a day's food

soared during the fifteenth and early sixteenth centuries, and then took a very long time (in some cases into the 1930s) to return to early fifteenth-century levels. Consequently, families worked more hours per year to make ends meet: men worked longer, more women worked for pay, and more children worked as well. One study suggests that the average work year for adult males rose over 20 percent in England just between 1760 and 1800. Though evidence elsewhere is spottier, a similar “industrious revolution” appears to have occurred in other parts of Europe, China, Japan, colonial North America, and perhaps parts of India. Meanwhile, slaves in the New World, particularly on sugar plantations, were being worked as hard as any labor force in history.

The slaves had no choice, but why did so many free or semifree people begin to work much harder? Some of them had no choice either: as birth rates rose there were more mouths to feed, and the availability of more laborers also tended to drive down workers’ earnings per day. But a cultural shift was at work, too.

With more days of work required just to earn the family’s food, people might have been expected to buy fewer nonessentials, or at least not more of them. But instead, ordinary people in various parts of the world appear to have purchased considerably more clothing, specialty and processed foods, and household goods and services in 1800 than in 1500. (Again, the evidence is most detailed for western Europe, but it points the same way for various parts of east Asia, North America, and perhaps elsewhere.) In other words, people worked more hours for the market, not just to get essentials, but to acquire various little luxuries: sugar, tobacco, silver jewelry, tableware, and more. This was mostly a matter of extensive growth, but it also relied in part on improvements in technology (more efficient shipping that facilitated trade, for instance) and changes in social organization, especially greater labor specialization. For instance, many people gave up making their own candles and began buying them instead, while putting the hours saved into making more of whatever they in turn specialized in (say, cloth) and selling it.

The resulting gains in efficiency from increased interdependence, though hard to measure, were considerable. And once again, extensive growth (more land and labor inputs) and intensive growth (social and cultural changes that created more efficient marketplaces with more attractive goods available, perhaps acting as incentives for people to work harder to get them) were so sufficiently intertwined that they are hard to separate. In fact more efficient labor markets may even have helped create the population growth that increased the labor supply. The gradual freeing of people in various places from forced labor obligations and restrictions on migration, improvements in the availability in labor markets of information about opportunities elsewhere, and greater opportunities for commoners to acquire land all meant it was easier for young people to start their own lives and families without waiting for their parents to give them land, or a shop, or some other productive asset. The result frequently was earlier marriage and higher birth rates. At the same time, denser population increased the possibilities for specialization—only a community of a certain size will support a full-time carpenter or weaver—and set the stage for intensive growth.

The increased long-distance trade that resulted from advances in navigation and shipping also fueled growth during the industrious revolution. Exotic new goods, mostly from the tropics, proliferated, and they were often at least mildly addictive: sugar, cocoa, tea, coffee, and tobacco. These fueled the emerging consumerism of people in Europe, China, and elsewhere, and generally had to be obtained through the market: of the crops listed above, only tobacco could be grown in the temperate zones where the largest and wealthiest collections of consumers were found. Meanwhile, potatoes, corn, and other new crops made food production possible in places where no known crop had grown before, especially at high elevations. Enormous new fisheries off the North American coast provided cheap protein. And the knowledge of strange new worlds—which was collected above all in Europe—did more than just provide practical new ideas; it also shattered old systems of knowledge,

intensifying the search for new ways to understand the natural world. The new thinking that emerged did not produce the modern sciences and science-based technologies until the nineteenth century; but when they did, they transformed almost every branch of economic activity.

This “industrious revolution,” however, could not go on forever, and it also did not yield vast increases in output per person. While global population doubled from 1500 to 1800, output perhaps tripled, so that output per person rose about 50 percent in three hundred years. The critical constraints were in the area of agroforestry and energy. Broadly speaking, all the basics of human life—food, construction materials, clothing fiber, and energy—came either from vegetative growth (grain, lumber, cotton or flax, firewood) or from plant-eating animals (meat, leather, animal locomotion), which meant from the combination of land, fresh water, and sun. Supplies of these could not be increased on demand, creating difficult trade-offs: more farmland, for instance, meant less forest, and thus less lumber and firewood. The result, in several of the most productive places in the world, was a serious energy shortage, which placed limits on economic growth.

The Industrial Revolution

The solution to this energy shortage was the development of fossil fuels: first coal (and to a lesser extent peat) and later oil and natural gas. While coal, in particular, had been used to some extent in many places over the centuries, Great Britain was the first society to use it on a truly massive scale for its everyday needs. A number of factors contributed to this. First of all, Britain had lots of coal, much of it very conveniently located. Second, it was badly deforested relatively early, making the switch to coal (and to stone for building) imperative. Third, technological developments, especially in metallurgy and precision boring, facilitated the development in England of the world’s first economically viable steam engines, which were essential to pumping water out of the coal mines. Without steam power, it has been estimated, British coal mining could not have expanded beyond its

An impoverished woman breastfeeds her baby in Tijuana, Mexico. A great disparity in wealth exists between the world’s poorest and richest citizens.
Photo by Kevin Connors (www.morguefile.com).

level in 1700; instead it multiplied sevenfold by 1815, and almost 100-fold by 1900. Coal mining elsewhere grew even faster in the late nineteenth century, albeit from a smaller base. And in the twentieth century, the increased use of oil and natural gas—fuels barely used at all before modern times—has made possible even more staggering increases. The average human uses ten to twenty times as much energy today as before the Industrial Revolution, and in rich countries, the figure is higher still.

The staggering quantities of energy thus made available, combined with a wave of other technological innovations, ushered in by far the greatest surge of intensive growth in human history—one that has continued for roughly two hundred years thus far, gradually spreading from a few pockets in Britain and elsewhere in northwestern Europe to much (though not all) of the world. While global population has risen a bit over 500 percent since 1800, economic output has risen over 4,000 percent; industrial

Commerce is the great civilizer. • Robert G. Ingersoll (1833–1899)

production may have risen 10,000 percent since 1750. About half of all economic growth in human history, as best as it can be measured, has occurred since 1950. Since that growth far exceeds the growth in land and labor inputs, most of it is a combination of additional capital inputs and intensive growth: technological and institutional changes that make labor, capital, and land use more efficient. It is very hard to measure the effects of capital apart from technology, since so much capital enters the economy in the form of new machines, but there is no doubt that much of this prodigious growth is intensive. The development of far more systematic natural sciences has led to a steady stream of new productivity-enhancing technologies. In earlier eras, by contrast, technological change usually came in the form of single innovations or small clusters, and exhausted itself when a boom in the innovative industry created a shortage of some particular material. (Improvements in metallurgy, for instance, often led to such massive deforestation that the metal works ran out of fuel.) And the advantages in military and political power that were conferred by industrialization were so great that governments everywhere tried to change their institutions to facilitate economic growth. Indeed, gross national product per person is probably the single most widely used index of the success or failure of societies in today's world—even though this measurement was invented only in the twentieth century, and most economists would agree it is only a very rough measure of human welfare. The United Nations' Human Development Index is an increasingly used alternative that seeks to measure human development factors beyond the realm of economics.

For all the diversity of technological changes involved, much of the story of post-1800 growth is that of the fossil fuel revolution in its many applications. It surfaces as transportation that has transformed the global division of labor (making it possible to a greater extent than ever before for people to depend on very distant places even for essentials), as chemical fertilizer and pesticides that have raised yields per acre to unheard-of levels (greatly reducing the extent to which the finite supply of land constrains

production), as plastics and other new materials that substitute for other resources, and as machinery that substitutes for the muscles of billions of people and animals. Thus labor supply does not currently limit production very much, either; the problem, on the contrary, is a surplus of workers, or workers who are not in the places where they are most needed.

Growth in the Contemporary World

While global wealth is very unequally distributed, and poverty remains a huge problem in much of the world, the modern economic era is unparalleled in at least two ways. First, the world economy has grown to the point where everybody could theoretically have more material goods than even the privileged had in most societies until quite recently. Second, the major constraints on even further growth are probably not so much the old ones of limited land, labor, and capital, as they are the environmental damage that may result from continued extension of our energy-intensive production methods. At the moment, the threat of global climate change from continued production of greenhouse gases (a by-product of all fossil-fuel burning) is probably the most widely discussed, but the long-term effects of making, burning, using, and dumping many other chemicals invented in the last two centuries—most of them, in one way or another, derivatives of coal or oil—pose a number of other poorly understood threats.

In the last few decades, major economies have become less fossil-fuel intensive, meaning they burn fewer fossil fuels per dollar of economic activity. Decreasing the energy intensity of the economy is also a high priority for China and India, two of the world's largest developing economies. But because the total amount of economic activity continues to grow, so do worldwide fossil fuel consumption, global warming, and various other kinds of environmental damage. It remains to be seen whether less-damaging energy sources can become a significant part of the world's power. None of this means we are likely to see an end to economic growth any time soon, but it does mean that how we think about growth and its costs may change. Even

intensive growth may no longer be the “free lunch” it has sometimes seemed to be. In combination with the global economic and financial crises that emerged out of the United States in 2007 and severely impacted economic growth throughout much of the world, the effects of climate change, such as resource scarcity, have raised some serious questions about sustainability and the pursuit of economic growth at any cost.

Ecumenicism

Generally, ecumenicism is associated with the Christian tendency to promote religious unity, but the term more loosely refers to a desire for global cooperation among all religions. Ecumenicism dates back as far as the split between Rome and Byzantium in 1054. In modern times, ecumenicism was seen during European colonial expansion and again as those colonies gained independence and began their search for religious freedom.

Ecumenicism refers to the striving for reconciliation and unity across the diversity of Christian denominations. To a lesser extent, it can also mean a looser goal of harmony among religions, both Christian and non-Christian. The term *ecumenicism* comes from the Greek word *oikoumene*, designating the entirety of the inhabited Earth (in the scope of Greek knowledge, roughly the lands from the western Mediterranean to India). It is one among many modes of universalistic thinking in world history.

Premodern Ecumenicism

The first wave of Christian ecumenicism occurred in the centuries after the split between Rome and Byzantium. The fairly short-lived unity of early Christendom had rested on the success of the Council of Nicaea (325 CE) and Constantinople (381 CE) in stamping out heretical sects, and of the far-reaching rule of the Roman Empire, which had adopted Christianity as its official religion in the fourth century. The division between the Latin West, centered on Rome, and the Orthodox East, centered on Byzantium, came to involve differences deeper than mere

politics: a divergence of ideas about state–church relations, the relative strength of Roman and Greek cultural legacies, and so on. When the crusades brought more intense contact between western and eastern Christendom, the greater visibility of contrasts only worsened the state of ill will. Ecumenical thinking in these centuries revolved around the perceived need to restore the unity of Christendom as one expanding community of believers defined by correct doctrine and loyalty to one organized church (in practice, given the greater Western interest in ecumenicism, the Catholic Church with its pontiff at Rome).

To a lesser extent, the same kind of thinking appeared in sixteenth- and seventeenth-century western Europe. The Protestant Reformation had put an end even to the unity of western Christendom, which had rested on the cultural-religious-intellectual syntheses of Aquinas, Dante, and the like. Despite these multiplying political and doctrinal divisions, the ideal of a single universe of believers lingered throughout Christianity's second millennium. Much as in the other major Eurasian civilizations, a fragmented reality was being measured against the standard of a unified golden age. It was believed that cleavages of nation, race, and class should properly yield to the ultimate solidarity of the faithful.

Of course, broader ecumenical patterns of thinking had long allowed intellectuals to imagine unity, or at least convergence, across the boundaries of sect and rite. Mystics within the world religions have often believed that ultimate spiritual truth, being higher than any doctrine or practice, cuts across the world religions. The most ecumenically

The Indian religious leader Swami Vivekananda played a leading role in bringing Hinduism to the attention of the Western world in the early 1900s.

minded groups have included world renouncers like the gnostics, the Sufis, and the Upanishadic forest dwellers. But even more mainstream theologians in each of the world religions have found ways to justify interreligious openness. For medieval Catholics, there was the idea that other religions, even if they lacked the crucial centrality of Jesus as savior, at least reflected natural law and an innate human tendency to seek the divine. Islam had a framework of respecting other religions, such as Judaism, Christianity, and Zoroastrianism, as legacies of earlier divine revelations that had become distorted over time. And the various branches of Hinduism tended to imagine all religions as alternative paths to the same goal. This kind of ecumenical openness has been a recurring theme in those world-historical encounters that go beyond trade and migration into the more challenging realm of intellectual dialogue. Religious cosmopolitans have always tried to step back from superficial differences of practice and

symbolism, to find common ground in divine or human nature. Examples include the interreligious councils of Akbar and Abu'l Fazl in Mughal India, and the entry of Jesuit missionaries to Confucian China in the 1500s.

Ecumenicism in Modernity

The twentieth century saw a second major wave of Christian ecumenicism. At first the need for a common front in European colonial missionary activity drove the search for unity, especially across the Protestant denominations. The 1910 World Missionary Conference at Edinburgh is often seen as the start of this ecumenicism. Later, the broadening of ecumenicism to encompass Protestant, Catholic, and Orthodox branches of Christianity responded to other pressures, like the crisis of secularization in the West. Many Christians saw fragmentation as due to petty squabbles, and as an obstacle in counteracting the broader decline of religious belief among the peoples of the developed world. Social and geographic mobility also increased many believers' desire to cross-denominational boundaries and do such things as take communion together.

In the later twentieth century, ecumenicism often took on a more leftist cast. The rise of national Christian churches in newly independent African and Asian countries broadened the base of transnational ecumenical bodies like the World Council of Churches. Issues of human rights, nuclear disarmament, and social equality figured more prominently in ecumenical circles from the 1960s onward. Efforts have aimed mainly at enhancing practical cooperation, moving toward mutual recognition of baptisms and marriages, and overcoming thorny debates over the historical roots of priestly authority. Ecumenicism has tended to draw support mainly from high-culture establishment versions of Christianity like Anglicanism and Catholicism, and from the more liberal currents like Unitarianism. Opposition has remained strong among Evangelicals and others who consider it misguided to downplay core doctrinal commitments, or who for

I love you when you bow in your mosque, kneel in your temple, pray in your church. For you and I are sons of one religion, and it is the spirit. • Kahlil Gibran (1883–1931)

Thomas S. Sinclair, *Christian Union* (c. 1845). Lithograph. Protestant clergymen officiate at the altar of the New World flanked by the lion and lamb, iconic symbols of Christianity, while a Native American man and an African slave gesture toward a dove, symbol of peace.

various reasons dislike the political agendas that ecumenicism has embraced. Often the strongest voices of present-day religious resurgence, such as born-again Christians, have affirmed their identities in a way that leaves little room for ecumenical bridge-building.

Broadening Horizons in World Religions

In the last few decades, the scope of ecumenicism has also expanded to include openness to non-Christian religions. Theological dialogues with Jews and

Muslims, who share many of the same historical and metaphysical reference points, are one example. The broadening of ecumenicism also reflects a growing Western interest, especially since midcentury, in Asian religious traditions such as Buddhism. Ecumenically minded clergy and laypersons alike often look beyond Christianity for sources of meaning in a disenchanted modern world, and for potential allies in an era of growing secularization. This interest in the non-Christian traditions is loosely analogous to the way the study of world history itself has been broadened, and the effort to overcome earlier Eurocentrism

in how Westerners made sense of their place in the world.

Education

Education—the process of learning and teaching—has taken many forms over millennia, from storytelling, oral instruction, and imitation in hunter-gatherer societies to the formal, specialized, and (often) lengthy schooling afforded students in today’s industrialized world. Although the history of education is traditionally told nation by nation, rather than from a global perspective, passing our collective knowledge to future generations is central to the human experience.

Education is a word used in many ways. Its Latin roots, *e* (“out”) and *ducere* (“to lead or draw”), suggest the meaning “to lead out or draw forth.” Education can be defined as learning and teaching, both informal (in daily life) and formal (schooling). Learning from experience and observation can occur without teaching, and, of course, teaching can occur without learning. Education can also mean the study of learning and teaching.

The Uniqueness of Humans

Learning, defined as modification in response to specific experience, certainly occurs in other animals; how far back hasn’t yet been determined. Other animal learning can be classical conditioning, as in Pavlov’s experiments, or operant conditioning, in which an animal is rewarded for chance behavior. It can be observational learning, or modeling, as birds learn their songs or wolves learn hunting behavior. A third kind of other animal learning, called insight learning, occurs when some animals

like chimpanzees, ravens, and other birds are able to solve problems the first time they encounter them. In every species the balance between genetically determined and learned behavior varies; humans are unique in the large portion of their behavior that is learned.

Humans are unique in other ways. Our capacity for language and communication far exceeds anything in the rest of the animal world. Our talent for syntactical, symbolic language permits us to exchange and pass on our knowledge so precisely that over time it accumulates. This talent, combined with the long dependency of juveniles on adults, has meant that humans accumulate collective learning in ways strikingly different from other animals. Since this is so, education lies at the heart of human life, in ways unlike those of any other animal, changing over time as human culture has evolved.

The Foraging (Paleolithic) Era

More than 95 percent of human history took place during the foraging (Paleolithic) era of hunter-gatherers, even if almost as many humans are alive now as during that entire period. Archeologists have found little to indicate how education took place in that society; we can only surmise based on knowledge of current hunter-gatherers.

Direct observation and imitation surely occurred during the foraging era. Given the human gift with language, however, storytelling and oral instruction must have played increasing roles in the education of the young as culture evolved. In the earliest years, when humans lived in small bands of twenty

Members of a Bushmen tribe keep alive the ancient tradition of handing down history through stories and song. Photo by Urša.

to sixty, young humans learned from their parents, extended family, and kin. As human societies expanded into tribes and chiefdoms, the young, as they reached puberty, must have experienced more structured social experiences, such as rituals and initiations.

Hunter-gatherers accomplished amazing feats: they migrated out of Africa into new environments around the world and survived harsh ice ages. To do this, they had to develop increasingly complex skills and to pass them on to their offspring. These skills included developing new tools and techniques, chipping stone tools, hunting large animals, creating sophisticated art, sewing furs into warm clothing, building shelters, cooking, and navigating terrain.

Two examples suggest the collective learning passed down by hunter-gatherers. The San bushmen of the Kalahari Desert in South Africa have survived for millennia. The women use a blanket and smaller carry bags, a hide sling, and an all-purpose wooden digging stick. The men use a bow and poison-tipped arrows, plus a small spear, to hunt small animals. They have named some 260 species of wild animals and collect more than 100 species of plants. The Inuit of Alaska and northern Canada have survived for millennia with fur clothing, canoes, and hunting equipment all made from stone, bone, tusk, and antlers. The techniques of San and Inuit adults, plus immense knowledge of their environment, are successfully passed to their children by means of imitation and direct oral instruction.

Education in Early Agricultural Societies

When people began domesticating plants and animals about ten thousand years ago, they also domesticated themselves to live in settled communities and tend their flocks and fields. Settling down into a village, and later into town life, constitutes the most significant change in human ways of life, the first step toward the high density and complexity of current human culture.

With village life people began manipulating nature, rather than simply relying on it. They increased their interaction with certain plants and animals, learning enough to take over their care and their genetic development. Collective learning began to accelerate; new tools (spades, scythes, mortar and pestle, hand axes, plows) and new techniques (carpentry, weaving, pottery, and religious practices) appeared. With settled life, people could support more children, and they needed them for labor. The human population began a steeper increase, estimated from less than 10 million to 50 million in the five thousand years from 8000 to 3000 BCE.

Yet no formal schooling emerged, as far as we know, nor any need for systems of writing. Everything known could still be passed down through observation and imitation, oral instruction, rituals, and storytelling. Gender roles were becoming more specialized, but otherwise people were still generalists; they had to learn at least most of skills assigned to their gender, which mostly took place within the household.

These assertions about learning and teaching during agricultural time are difficult to substantiate. Archeologists do not find evidence of how education took place before written records and substantial buildings. We can only surmise based on what is known from the archeological record about life in agricultural times and from current examples of agricultural societies, none of which is entirely free of the influence of modern life.

Education in Early Civilizations

As populations increased in density and towns grew into cities, some human societies began to take on

A section of the Diamond Sutra scroll (c. 868 CE), the oldest known printed and dated book in the world, was discovered in China's Dunhuang caves in the early twentieth century.

a constellation of new characteristics. These societies are technically called civilizations, or agrarian civilizations to emphasize their dependence on their surrounding agriculture. This happened all over the world, largely independently. Early agrarian civilizations include Sumer (about 3200 BCE), Egypt (about 3100 BCE), the Indus Valley (about 2300 BCE), northern China about 1700 BCE, the Classic Maya (250–800 CE), the Aztecs (late fifteenth century to early sixteenth century CE), and the Inca in the Andes (early sixteenth century CE).

Not all of these early agrarian civilizations shared exactly the same characteristics, but all had a high density of population concentrated in cities, a surplus of food, ranked social stratification, specialized occupations, and coercive forms of taxation. Most developed a system of writing and notation. With this transformation of human society came a transformation of education: formal schooling emerged as apprenticeships developed for learning specialized occupations, and schooling was organized for the tiny elite fraction of the population who learn to read and write.

Schooling often began by being attached to the royal court; sons of nobles joined the kings' sons in

learning law and administration. For example, in Egypt the only school in the Old Kingdom (c. 2575–2150 BCE) was attached to the royal court. As the need for scribes and administration increased, other small schools appeared where boys studied from age five to ten, and then were apprenticed in administration. From the mid-third millennia BCE to the mid-second millennia BCE the number of literate Egyptians probably would not have exceeded 1 percent.

For an early civilization, the Aztecs were unusual in having mandatory schooling for all—girls as well as boys. Every *calpolli*, or ward of related families, had its own schools, of which there were two kinds. Young commoner women attended *cuicacalli*, or houses of song, to learn songs, dances, domestic crafts, and childrearing. Young commoner men were trained to be warriors. Every *calpolli* had to provide four hundred soldiers under command of its own officers, trained at a school called a *telpochcalli*. Boys started school at puberty and attended until their midtwenties, when they withdrew to marry. Students ate with their families, but slept at the school, to avoid drunkenness and sexual license. They first entered battle at age twenty. Sons of nobles attended different

schools (*calmecac*) attached to temples, where they received more intensive administrative and religious education in addition to military training. Sons of gold workers and feather workers learned the details of Aztec religious iconography by attending schools for nobles or their own version of such schools.

Education in Developed Civilizations

As civilizations developed around the world, many schools and learning centers still depended on state or imperial governments and on religious institutions, but a few were independent entities; free public schools sprang up in China in the late thirteenth century under one Mongol ruler of the Yuan dynasty who believed it would improve everyone's lives.

India

As agrarian civilizations developed in Afro-Eurasia, large-scale religion also developed with the spread of literacy beyond the royal courts—Hinduism, Buddhism, Confucianism, Judaism, Christianity, and Islam. These religions set up centers of learning, as exemplified by Taxila, a Hindu and Buddhist center near the present city of Islamabad, established in the sixth century BCE. The greatest Indian center of learning, Nalanda, in eastern India near Nepal, was founded as a Buddhist monastery in the fifth century CE and grew to house up to ten thousand students, flourishing until the twelfth century CE. It attracted students from Turkey to Korea, with a nine-story library housing hundreds of thousands of volumes.

Greece and Rome

In the classical Greek city-states of Athens and Sparta, strikingly different modes of education were available. In Athens the state provided two years of military training. Other education was private; anyone could open schools and charge tuition. Girls rarely received any education. Schools of higher education developed—the Platonic Academy by Plato and the Lyceum founded by Aristotle. In Sparta girls did receive a formal state education and boys were taken

at age seven to school dormitories and taught little other than sports and fighting. Literacy in classical Greece is estimated at no more than 5 percent. Rome had many private schools charging admission by the second century BCE; there literacy rose to probably not more than 10 percent.

China

During the Zhou dynasty (1045–256 BCE) China had five “national” schools for aristocrats and nobility. Confucius formulated his ideas in the early fifth century BCE, and by 124 BCE the Emperor Han Wudi set up an Imperial Academy based on a curriculum of the Five Classics of Confucius. A civil service nomination system, set up during the third century CE, developed during three more centuries into an imperial examination system, which gave rise to schools that taught the Chinese classics. This system was used until 1905, except when interrupted under Mongol rule of China. Khubilai Khan (reigned 1260–1294) believed that free public education for all children could improve everyone's quality of life. His government created many public schools, which used colloquial rather than classical Chinese to help students learn faster.

Two Chinese innovations—papermaking and printing—had implications of global dimensions for the exchange of information, mass literacy, administration, and scholarship. A court official, Cai Lun, developed paper production in the early second century CE. Experiments in woodblock printing began about 600 CE, and by the eleventh century the Chinese printed some texts with movable ceramic types that were affixed to a metal plate and rubbed by hand on paper—but they did not put this technique into general use. Papermaking spread to Korea and Vietnam by the fourth century, to Japan and India by the seventh, to the Islamic world by the eighth, to Muslim Spain by 1150, to France and Germany in the 1300s, and to England in the 1490s. Printing reached Korea (where types were sometimes made of bronze) and Japan, but it was resisted by the Islamic world, which valued handwritten calligraphy, and was delayed in Europe because of the absence of paper until the

fourteenth century. Johannes Gutenberg developed movable type from metal alloy in the fifteenth century; it is not clear whether he was aware of Chinese and Korean precedents.

Islamic World

By the sixth century CE Persia had a flourishing Academy in the city of Gundishapur, the intellectual center of the Sasanid dynasty (224/228–651 CE). It included Zoroastrian, Persian, Greek, and Indian learning, especially in medicine. For the ninth through thirteenth centuries the intellectual center moved to Baghdad, built in the 760s just as the process of papermaking was learned from Chinese prisoners of war. Cultured Muslims were devoted to books, substituting linen rags, beaten to pulp, for the hemp or mulberry bark used in China. In early Islamic days mosques carried out schooling, but by the ninth century schools became separate from mosques. Called *madrasas*, these schools granted academic degrees at various levels and are sometimes called the first universities, though they were more like colleges. Probably Arab scholars carried out the most advanced science in the world from about 800 to 1400 CE.

In the fifteenth and sixteenth centuries Timbuktu (now often spelled Timbuctou), in the current West Africa nation of Mali, became an Islamic center of learning. It was home to Sankore University and other *madrasas*, whose primary focus was on the Qur'an

but also included logic, astronomy, and history. More than 100,000 manuscripts were held in libraries in Timbuktu.

Europe

After the disappearance of the Roman Empire, monasteries of the Catholic Church were centers of learning in Europe. The first emperor who united most of Europe after the Romans, Charlemagne, king of Franks (reigned 768–814 CE), provided for monastic schools and centers for book copying. Monasteries in the twelfth and thirteenth centuries, particularly in Spain, provided a large number of Greek and Arabic translations, especially in medicine and science. Universities emerged in Europe from the early second millennium. They enjoyed unusual autonomy from both church and state as separate corporations in charge of themselves, in contrast to Chinese and Islamic centers of higher learning. In the early twelfth century the Catholic Church mandated that every cathedral provide free education for poor boys. Gradually by the sixteenth to eighteenth centuries, education became more widespread.

Education in Modern Industrial Nations

When the explorations of Spanish and Portuguese sailors joined the world's two hemispheres, a new era of world history began. It produced another turning point in world history, the Industrial Revolution, characterized by the burning of fossil fuels and the surplus of resource extraction beyond even rapid population growth. Unlike the agricultural revolution, the Industrial Revolution emerged independently in only one place (Britain) and spread first to nearby or related places in western Europe and the United States, with a resulting domination of the world by Western nations through the twentieth century.

The Industrial Revolution fostered the development of the modern nation-state, with its increased bureaucracy and involvement in the daily life of its citizens, upon whose support the state increasingly depended. Education for political participation became a vital

part of industrialization. In Europe and the United States, as industrialization spread in the nineteenth century and child labor laws were enacted, most governments began to provide free compulsory primary education for all their citizens, giving the state power to remove children from the tutelage of their parents for part of the time. In Japan, under the Tokugawa shogunate (1600/1603–1868), samurai leaders provided sufficient schools to achieve a literacy rate of about 40 percent by 1848, a condition that helped Japan begin rapid industrialization. In Russia, with a literacy rate less than 30 percent at the beginning of the twentieth century, the new Communist government in 1919 focused on universal compulsory education for children and literacy for adults, achieving about 70 percent literacy by 1936.

The demand for formal education in industrial societies has not ceased. By the late nineteenth and early twentieth century industrializing governments began to add compulsory secondary education and to develop their universities into larger institutions with much more research capacity. Oral traditions and teaching by example continue to be used, of course, although they are often not even considered to be education.

Trends for the Future

As can be seen in this brief account, the complexity of the educational enterprise has increased over time. The length of childhood and of initial learning, notably long in humans to begin with, has been extended in industrial societies and now may last longer than the entire average lifespan two hundred years ago. Lifelong learning is a growing trend. Education has become in modern times central to industrialization and the human effort at productivity, as it has always been central to human survival.

This article constitutes a most preliminary sketch of the history of education, which has yet to be told from a global perspective, rather than nation by nation. Yet even this brief sketch reveals the cooperative behavior required to pass on collective learning to succeeding generations and the centrality of education to the human experience.

Egypt

Africa's Nile River allowed Egypt to emerge, beginning from the sixth millennia BCE, as one of the world's first hydraulic civilizations. Building canals and dikes, Egypt developed a redistributive economy and a complexly ordered, unified society under one king by 2950 BCE. Even as a part of other empires in other eras, Egypt became an icon of Western civilization, with a distinctive artistic canon recognizable today by the general public

Egypt has long been accorded a paramount place in world history. This is particularly true of ancient Egypt, which has exerted a powerful influence on both popular and scholarly imaginations to the point that it has been incorporated into the standard view of Western civilization. Other epochs in Egyptian history were also of great importance, however, and not only to Egypt but also to the history of the world.

The Gift of the Nile

As the climate of northeastern Africa dried out during the Holocene period, the peoples of the region had to move to wetter areas, either to the south or to the east to the Nile Valley. By the sixth millennium BCE, most of Egypt's population had migrated to the valley of the Nile, a remarkable river that was the material basis for Egyptian civilization. Besides providing almost all of Egypt's water, the Nile annually inundated the fertile land along its banks, leaving behind pools, depositing new soil, and washing away excess minerals, thereby avoiding the salinization that was the bane of other hydraulic civilizations such as ancient Mesopotamia. The river was continuously

navigable throughout Egypt, from the broad delta in the north to the first cataract at Aswan, 900 kilometers (559 miles) to the south, providing ready communication and the means to convey heavy loads over long distances. (A cataract, of which the entire Nile has six, is a place where boulders break the water's surface or where rapids flow; boats pass them only with difficulty.) The river was ideal for sailing craft: the steady current carried vessels north while the prevailing north wind propelled them south. Even today 95 percent of Egypt's population lives within a few kilometers of the river.

This was the matrix from which one of the world's first hydraulic civilizations emerged. During Predynastic times (c. 5300–2950 BCE) increasingly complex social and political organizations developed to manage and maximize the river's gift through construction of canals, dikes, and artificial pools, and through water-raising devices. Control of the resulting agricultural surpluses enabled an exploitative elite to establish a redistributive economy with increasing social stratification and differentiation of labor. A series of kingdoms developed along the Nile, growing ever larger and inevitably coming into conflict with each other and consolidating into still larger kingdoms. Little is known about the process apart from what can be interpreted from enigmatic artistic representations on items such as ceremonial palettes and maces, although it is fairly clear that the unifying impulse came from the south. By 2950 BCE at the latest, Egypt was united under one king, providing one of the earliest models of state formation, and one unmatched in scale by any of its preceding or contemporary societies.

From the intensely innovative and creative experiences of Late Predynastic and early pharaonic

times emerged fixed forms of social usage, religion, and artistic expression so suitable to the Egyptians that they remained fixed for thousands of years. At the apex of society was the king, or pharaoh, who ruled with the status of a god. Monumental accomplishments such as the vast pyramid fields of Giza, Saqqara, and Dahshur demonstrated his command of the kingdom's people and resources. Highly complex systems of religion and magic connected people with the universe and assigned them a place in this life and the next, for which they made elaborate preparation through mummification and tomb construction. Ethical values such as *ma'at*, which might be loosely translated as *justice* or *truth*, guided personal and official conduct. Prodigious artistic production was regulated by an artistic canon that produced works so distinctive that they are readily recognizable today as ancient Egyptian, even by the general public. Stimulated by the need to keep royal records, the art of writing appeared early in Egypt and was expressed in stately hieroglyphic script by a privileged group of learned scribes. Through its monuments, art, and literature, ancient Egypt communicated a compelling impression of itself to succeeding ages.

During the Old Kingdom and Middle Kingdom periods (c. 2613–1640 BCE), Egypt functioned largely as a cultural oasis, separated from the rest of the world by deserts, restricted land approaches, and lack of a natural seaport. The ancient Egyptians probably felt little need for external contact, but cultural self-sufficiency can lead to complacency and technological backwardness, as was made apparent by the invasion and domination of Egypt by the foreign Hyksos during the Second Intermediate Period (c. 1640–1550 BCE). That humiliating episode prompted the Egyptians to import innovations such as the horse-drawn chariot, the curved sword, the compound bow, and body armor, as well as improved looms and potters' wheels, and superior strains of plants and animals.

With the resurgent New Kingdom (c. 1550–1069 BCE), whose monumental remains are so abundant at ancient Thebes (present-day Luxor), Egypt developed closer outside ties as it acquired imperial possessions in Syria through the campaigns of monarchs such

as Thutmose III and Ramses II. The emergence of other powers in the Near East required maintenance of diplomatic contacts, as is shown by the archives of the heretic king Akhenaten. Diplomacy became even more important during the Third Intermediate and Late Periods (c. 1069–332 BCE) when Egypt was often internally divided and occasionally subjected by foreign entities such as the Nubians, the Assyrians, and the Persians. A Greek merchant presence penetrated into the delta, and Greek mercenaries served in Egypt. Greek scholars and travelers were drawn to Egypt, including the fifth century BCE historian Herodotus who famously observed that "Egypt is the gift of the Nile." Egyptian influences on Greek art are obvious in sculpture and architecture.

Alexandria, the Ptolemies, and Rome

Egypt had fallen under Persian domination when Alexander of Macedon (Alexander the Great) arrived in 332 BCE. Alexander soon departed to complete his conquest of the Persian Empire, but not before establishing a new city, Alexandria, which provided a major seaport to a country that previously had none and firmly connected Egypt to the Mediterranean world. Out of the struggle for power following Alexander's death in 323 BCE, one of his Macedonian generals, Ptolemy, son of Lagus, secured Egypt for himself and his descendants, establishing a dynasty that lasted three centuries. Although the Ptolemies presented and justified their rule through traditional pharaonic trappings to the masses of Egyptians, they superimposed a Greek-speaking elite class and its foreign culture on Egypt.

The Ptolemies ruled the most powerful state in the eastern Mediterranean, an empire that extended far beyond Egypt, and that was usually able to hold its own and more with its chief rival, Seleucid Syria, another product of the breakup of Alexander's ephemeral empire. The immense, ever-renewed resources of Egypt enabled the Ptolemies not only to maintain their military power but also to sustain magnificent achievements in material culture and intellectual life. Alexandria became by far the greatest city of the eastern Mediterranean. Its two harbors, guarded by the

Lighthouse, teemed with commercial and military vessels. The city was filled with thousands of sumptuous palaces, temples, and public buildings. The Museum became the intellectual center of the Mediterranean world, attracting the greatest scholars and the best collection of books to its incomparable Library.

Under its first three kings—Ptolemy I Soter, Ptolemy II Philadelphus, and Ptolemy III Euergetes—who reigned from 306 to 221 BCE, the Ptolemaic dynasty retained its preeminence, but later rulers were often less capable, and at times the dynasty fell into unscrupulous hands. Rome emerged from the Second Punic War (218–202 BCE) as the strongest power in the Mediterranean and progressively extended its sway eastward, interfering increasingly in Egypt's affairs throughout the second century BCE. By the following century Egypt was virtually a Roman puppet state. Cleopatra VII (r. 51–30 BCE) attempted to exploit internal Roman competition for power to reassert the independence of her kingdom, hence her liaisons with Julius Caesar and Marcus Antonius. In the end, however, the faction led by Octavian, later styled Augustus, prevailed. Egypt became a Roman province in 30 BCE.

If anything, the Roman Empire exploited Egypt more ruthlessly than had the Ptolemies. Besides substantial taxes, Egypt regularly shipped vast quantities of grain to Rome, the first of several times that Egypt served as the breadbasket of a

foreign power. By the second century CE the Egyptian economy was experiencing severe stress from the burdens imposed on it. But Egypt also exerted a strong allure on the Roman Empire. The several Egyptian obelisks that were transported to Italy served as reminders of the ancient land through the centuries. Egyptian religious cults such as that of Serapis and Isis spread through the empire. Alexandria remained supreme in intellectual life. Ideas in geography, astronomy, and medicine that were nurtured there circulated in both the West and the Middle East as late as the nineteenth century. Alexandria was foremost in philosophy, being especially notable in the development of Neoplatonism. Another cultural product of Roman Egypt, Hermeticism—a mix of philosophy, metaphysics, alchemy, and astrology that was based on the mythical Hermes Trismegistus—was particularly influential during the European Renaissance. But when the Roman Empire entered a period of extended crisis during the third century CE, probably no province suffered as much as Egypt, weakening old certainties and institutions while opening the way for new ones.

Though usually underappreciated by Christians in general, Egypt played a central role in the establishment and spread of Christianity. Much of Christian orthodoxy was initially hammered out in Egypt; the Nicene Creed, for example—“I believe in one God, the Father Almighty, Maker of all things both visible and invisible, and in one Lord Jesus Christ, the Word of God”—was formulated by Egyptian churchmen; the New Testament in its canonical form was first compiled in Egypt; and Egypt contributed greatly to

the development of many of the church’s most important institutions such as monasticism. Traditionally brought to Egypt by Saint Mark, the early development of Christianity in Egypt is obscure, but there can be no doubt that the new religion found fertile soil along the banks of the Nile. The vicissitudes of the third century only made it grow stronger as people turned to it for comfort and support. By the late fourth century, through a combination of conversion, aggressively antipagan measures, and imperial favor, the religion had triumphed. Egypt became almost monolithically Christian.

Byzantines, Persians, and Muslims

With the collapse of the Western Roman Empire at the end of the fifth century, Egypt remained a province

of the Eastern or Byzantine Empire. As before, it was regarded as an imperial breadbasket, although the grain shipments went to Constantinople (later called Istanbul), not Rome. Relations between Constantinople and Egypt were far from smooth as irreconcilable areas of conflict developed. Alexandria, the preeminent city of the eastern Mediterranean for more than six centuries, resented its displacement by the upstart capital of Constantinople. Worse, the imperial capital began to assert theological as well political supremacy. Egyptian resentment was exacerbated by the emergence of serious doctrinal differences that found expression during the great church councils of the first half of the fifth century in disputes over matters such as monophysitism, the belief that Christ’s humanity is absorbed by his deity; thus he has only one nature, not two. Imperial attempts to impose its ideas of orthodoxy were vigorously resisted in Egypt.

At the beginning of the seventh century, the Byzantine Empire fell into a bloody civil war that devastated Egypt. Hardly had that conflict been resolved when the Byzantine and Persian empires began a prolonged struggle during which Egypt endured a sustained Persian occupation before the Byzantines finally prevailed. The Byzantine Empire was badly shaken by its conflict, however, and had difficulty in reimposing its rule in Egypt or even in protecting its borders against a new and totally unexpected force. United under the banner of Islam, Arab armies emerged from the Arabian Peninsula and drove the Byzantines from Syria in 636 CE, isolating Egypt from the imperial center. In 639, a small Arab force marched south from Syria to Egypt. An incompetent Byzantine defense and the welcoming attitude of the Egyptian people, who saw the Arabs as liberators from their hated oppressors, quickly delivered the province to the Arabs.

The consequences of the Muslim conquest of Egypt were momentous. One consequence, of course, was the establishment of Islam in Egypt, which became a predominantly Muslim land, although Egypt retains to this day a substantial Christian minority. Another consequence was Egypt’s adoption of the Arabic language. And an entirely new capital, Fustat, was established near the apex of the Nile Delta, displacing

Alexandria as the center of government and beginning the long decline of the latter city until its resurgence in the nineteenth century.

Thus Egypt became part of a new world empire, governed first from Arabia, then from Damascus under the Umayyad dynasty (661–750 CE). When the Umayyads were overthrown by the Abbasids in 750, the last Umayyad caliph, Marwan II, made his final stand in Egypt. After the Abbasids established a new imperial capital at Baghdad, Egypt became more peripheral and was usually loosely governed, especially as the authority of the Abbasid caliphate steadily diminished. That made Egypt vulnerable to the ambitions of a rival Shi'a Fatimid caliphate that had established itself in present-day Tunisia and was determined to wrest control of the Islamic world from the Sunni Abbasid caliphate in Baghdad. Egypt was the logical first step.

Fatimids, Mamluks, and Ottomans

Through a combination of effective propaganda and Abbasid weakness, at a moment when Egypt was riven with internal divisions, the Fatimids took Egypt almost without opposition in 969. The new dynasty immediately founded a new city a short distance north of Fustat, which became known as Cairo, although Fustat remained of major importance until it was destroyed during a crusader invasion in 1168. Once again Egypt was the center of a major empire, well led and capably administered, and strong both militarily and economically. Fatimid gold coinage, which retained its value almost to the end of the dynasty, set the monetary standard in the eastern Mediterranean and the Middle East. But the Fatimids never achieved their ambition of destroying the Abbasid caliphate, and less able rulers in less favorable times were hard pressed to meet a new and unexpected challenge in the Middle East.

Egypt does not come readily to mind when thinking of the crusades, which were ostensibly aimed at the Holy Land, but it was involved in them from beginning to end. An Egyptian Fatimid garrison lost Jerusalem to the First Crusade in 1099, and an Egyptian Mamluk army expelled the crusaders from the Asian

mainland at the end of the thirteenth century. Several major crusading efforts were primarily directed not at the Holy Land but at Egypt, and on more than one occasion the crusaders came close to success. At such a moment of crisis Salah al-Din, known in the West as Saladin, displaced the enfeebled Fatimid dynasty. Salah al-Din turned back the crusader threat to Egypt and recaptured Jerusalem in 1197. His rivalry with Richard the Lionheart during the subsequent Third Crusade became the stuff of chivalric legend. In Egypt he returned the land to the Sunni fold and established the Citadel, one of Cairo's major features. He ruled as sultan, paying lip service to the authority of the Abbasid caliph in Baghdad. The dynasty that he established, with extensive holdings in Syria as well as Egypt, is called the Ayyubid.

The Ayyubid realms were never functionally integrated, however, and they often failed to support each other effectively. When the French king Louis IX invaded Egypt in 1249 at the head of a strong army, it appeared almost certain that he would succeed. What saved Egypt was a new force of slave soldiers, the Mamluks (literally "owned men"). These formidable warriors met the French at the deltan town of Mansura, defeated them, took Louis IX captive, and turned back the last major crusader threat to Egypt. Within a few years the Mamluks again proved their mettle when the Mongols were about to invade Egypt having recently devastated Baghdad and killed the caliph. After dealing similar destruction to Damascus, the Mongols demanded that Egypt surrender or suffer a similar fate. Not waiting for invasion, the Mamluks rode north into Palestine and engaged the hitherto invincible Mongols at Ain Julut in 1260, defeating them utterly and chasing them out of the region. Within a few decades more the Mamluks had also conquered the last crusader stronghold on the Asian mainland. A crusader or Mongol conquest of Egypt would have had incalculable consequences not only for Egypt but also for world history.

Slave soldiers had long been a factor in Islamic governments. In Egypt the Mamluks institutionalized themselves as the dominant force with one of their

number ruling as sultan. Their ranks were replenished by fresh supplies of slave youths from beyond the Muslim world who were brought to Egypt and raised in the arts of war and instructed in Islam from childhood. From slavery they could rise high in the Mamluk hierarchy, commanding groups of Mamluk soldiers, even becoming the sultan. But the system was not hereditary. The only way to become a Mamluk was to enter the system as a slave. Full-fledged warriors and their military establishments were supported by the revenues from extensive grants of land. Yet, for all their warlike orientation, the Mamluks were great patrons of the arts, especially architecture. Many splendid Mamluk buildings still adorn Cairo.

In its heyday, the Mamluk Empire was the mightiest state in the Middle East, but a number of factors attenuated their strength over time. The Black Death, the horrific outbreak of bubonic plague that appeared in 1347, hit Egypt especially hard, destroying perhaps a third of the population, dealing a devastating blow to the economic foundations of the Mamluk system and depleting Mamluk numbers. Plague reappeared with such regularity in Egypt over the next five centuries that Egypt became intimately associated with the disease in the Western imagination. But the Mamluk system also deteriorated

from within as its unique training system lost its rigor. New innovations in tactics and military technology were ignored. The Mamluks never successfully adopted artillery, and they despised handguns as unworthy of mounted warriors. This made them vulnerable to the expanding Ottoman Turks who eagerly embraced new military techniques and weapons. After the decisive battle at Marj Dabiq in 1516, Egypt became a province of the Ottoman Empire and remained so in one form or another for four centuries.

Once again Egypt was relegated to the periphery as imperial policy was directed from Istanbul, as Constantinople was now called, and administered within Egypt by a long series of Ottoman governors. Relatively little is known about the first two centuries of Ottoman Egypt because of a dearth of historical sources, but it is clear that Egypt derived some benefit from being part of the extensive Ottoman imperial and commercial systems. Egypt particularly profited from becoming a transshipment point in the coffee trade as that new beverage gained avid markets throughout the Mediterranean and in Europe. Ottoman rule was light in Egypt, allowing the resurgence of the Mamluks as a privileged economic and military power. Eventually these neo-Mamluks became so powerful that they, not the Ottoman governors, were paramount within the land. It was in the wake of a failed attempt to reassert effective imperial authority at the end of the eighteenth century that another disruptive force intruded into Egyptian affairs.

French and British Intervention

At the direction of the revolutionary government of France, General Napoleon Bonaparte invaded Egypt in 1798. The intentions were to sever Britain's overland ties with India and secure Egypt and its agricultural riches for France. The ambitious young general may also have dreamed of winning an eastern empire for himself. But after some early but superficial successes, the situation became hopeless; Napoleon abandoned his army to seek greater things in Paris, and the French were expelled from Egypt by British

Zangaki, *Sphinx et la grande pyramide* (c. 1870s). Albumen print. The Sphinx in Jizah, Egypt, is a powerful symbol of the Egyptian state, past and present.

and Ottoman forces in 1801. The British evacuated soon after. But Egypt had become firmly fixed in Europe's political and diplomatic sights.

Another consequence of Napoleon's Egyptian expedition was the European rediscovery of ancient Egypt. This was initiated to a large degree by the scholars who accompanied the French expedition but was quickly taken up by droves of scholars and travelers, intently followed by a growing reading public in Europe that was fascinated by the resulting flood of publications and the intriguing objects from Egypt that were filling Western museums. By the end of the nineteenth century, Egyptology was becoming a highly institutionalized discipline, one with appeal far beyond the scholarly community. The impact of ancient Egypt on the popular imagination is difficult to overstate. Probably no other vanished civilization has exerted so powerful an allure.

It was reasonably assumed that Ottoman authority would be reestablished in Egypt in the wake of the Napoleonic expedition, but the unexpected again intruded. Muhammad Ali (1769–1849), an Albanian officer in command of one of the Ottoman contingents sent to Egypt, exploited the chaotic situation to establish a personal ascendancy and compel a reluctant Ottoman sultan to grant him the office of pasha, or governor, of Egypt in 1805, which he held until his death in 1849. Steadily consolidating his power, Muhammad Ali exterminated the odious Mamluks and imposed a degree of order on Egypt unknown for centuries. Through ruthless measures he greatly

increased the productivity of the country, built a powerful army and navy, and established industries in Egypt. Though nominally loyal to his master, the Ottoman sultan in Istanbul, Muhammad Ali was in fact much more powerful than the sultan with whom he fought two successful wars. So successful was he that the Western powers intervened to prevent the dissolution of the Ottoman Empire—and because of resentment that a non-Western polity could accomplish so much. Muhammad Ali was compelled to dismantle most of his military and industrial establishments, but in return he was granted the hereditary right of rule in Egypt for himself and his family, who retained it until 1952.

But Muhammad Ali's successors fell increasingly under the sway of the West. Ismail, who ruled with the exalted title of khedive from 1863 to 1879, pursued an especially ruinous policy of borrowing from Western bankers at usurious terms. Debts mounted to unsustainable levels to finance grandiose projects. The most expensive was the Suez Canal, which opened in 1869, but only brought more debt to Egypt while greatly enhancing the importance of the country to covetous imperialist eyes. When debts mounted to levels where the Egyptian government could no longer pay, European governments intervened to take control of the country's finances. That provoked a nationalist rising which Britain crushed militarily in 1882.

British intervention in Egypt was initially intended to be temporary, but it lasted more than seventy years. Withdrawal would mean the return of unacceptable conditions in Egypt—and leave Egypt and the Suez Canal, which had become Britain's lifeline to India, vulnerable to other predatory imperialist powers—so the British occupation became institutionalized. Although Britain maintained the diplomatic fiction that it ruled Egypt in the interests of the Ottoman Empire, Egypt was very much part of the British Empire.

The British accomplished much in Egypt in the area of administrative reform, and they thoroughly overhauled the vital irrigation system, with highly beneficial results. But they largely deprived Egyptian officials of administrative responsibility and

An illustration of an Egyptian tomb painting shows Ramses II and his sons attacking a mountaintop fort.

experience, while discouraging industrialization in favor of agriculture, causing Egypt to fall ever further behind. Education stagnated as the British refused to devote substantial resources to it at any level. Not until 1908 was a national university established in Egypt. Lord Cromer, the British consul-general and de facto ruler of Egypt, calculated that the Egyptians would be so grateful for the efficiency of British control that they would acquiesce in it indefinitely. When that calculation proved mistaken during the first decade of the twentieth century, reluctant steps were taken towards the establishment of a representative parliamentary democracy. But just as that promising process was being implemented, World War I broke out, and Britain found itself at war not only with the German Empire but with the Ottoman Empire as well.

The British were more firmly in control than ever as they suspended Egyptian political activity and imposed a state of emergency. Since they could no longer maintain the fiction of governing in the interests of the Ottoman Empire, they established a formal protectorate in Egypt. The Ottoman menace to the Suez Canal required large numbers of British soldiers to be stationed in Egypt. The country was compelled to make heavy contributions of produce, money, and manpower to the war effort—although Egyptians were not conscripted into the army in large numbers because the British did not want to create a large cadre of trained Egyptian fighting men.

At the conclusion of World War I, to which Egypt had so heavily contributed, and inspired by talk of

national self-determination, Egyptians expected their national concerns to be taken seriously. When they learned that their case was not even being considered and that the British intended to continue the protectorate, the country exploded. Realizing that Egypt had become ungovernable, Britain granted independence to Egypt in 1922, but with reservations. These included continued military presence in the canal zone and deferment of the final disposition of Sudan, which the Egyptians considered theirs by right of conquest but which had effectively functioned as a separate British colony since 1899. Britain also reserved the right to intervene to defend Egypt. The result might be better described as autonomy rather than full independence.

Constitutional Monarchy

The constitutional monarchy that was established in 1923 confronted serious problems from the outset. The new king, Fouad I, a descendent of Muhammad Ali, inclined towards autocracy whereas the parliamentary leaders wanted to exert genuine authority. Given time, political realities would probably have produced a working relationship between the two, but a third factor, repeated British interference, prevented the emergence of equilibrium. Even so, modest advances were made in areas such as education and the economy, although lack of investment capital inhibited development, as did the Great Depression. Intellectual and cultural life flourished. Nor was the political scene

altogether devoid of accomplishment. A treaty was negotiated in 1936 that provided for full Egyptian sovereignty and British withdrawal from Egypt, albeit after twenty years.

But with the outbreak of World War II in 1939, the British presence returned full force, for Egypt was of immense strategic importance. Threats from neighboring Italian colonies were turned back early on, but two German offensives in North Africa presented much more serious dangers, especially the second, which was stopped at al-Alamein, just one hundred kilometers (about 62 miles) from Alexandria. The British victory there narrowly prevented the Germans from capturing the Suez Canal and breaking into the Middle East and beyond. Egypt bore less of a burden in this war than in the previous one, but the Egyptians bitterly resented the way their government was coerced into cooperation by the British.

The postwar political situation in Egypt was dismal. King Farouk, who succeeded his father in 1936, degenerated into a caricature of depravity. Parliamentary politics were tarred by corruption, and the political spectrum became increasingly fragmented. Military intervention against the new nation of Israel resulted in a humiliating disaster, further discrediting a government that was increasingly out of control. Attempts at reform came too little and too late. The monarchy was overthrown by a military coup in the summer of 1952.

The figure that emerged supreme was an officer named Gamal Abdel Nasser, who held the office of president until his death in 1970. Determined to make a clean break with the past, the new regime extensively and repeatedly reorganized Egypt's political and economic systems, introducing a system of state socialism and an outwardly democratic system, but one in which the president was supreme. The British finally withdrew from Egypt in 1956 but returned later that year in an ill-advised joint British-French-Israeli invasion when Nasser nationalized the Suez Canal to pay for construction of the High Dam at Aswan. Britain's failure in the Suez crisis underscored that nation's decline as a world power. The

British were, however, able to prevent the union of Sudan with Egypt, a point of departure with enormous consequences for both nations. Enhanced in prestige after Suez, Egypt played a prominent role on the world stage during the 1950s and 1960s, with implications for the Cold War, the nonaligned movement, and especially for the Arab world where Egypt asserted a prominent leadership position. But that and Nasser's espousal of the Palestinian cause led to Egypt's disastrous defeat when Israel attacked in June 1967.

Under its next two presidents, Egypt gradually changed course in a number of significant ways. Anwar Sadat's surprise attack on Israeli forces along the canal zone in October 1973 achieved some initial successes and recovered sufficient prestige to enable Egypt to make a peace treaty with Israel that recovered territories lost in 1967, but at the price of alienation from other Arab countries who resented Egypt's abandonment of a united front against Israel. Sadat also began the process of moving away from a closed system of state socialism toward economic reengagement with the rest of the world. But he alienated many conservative elements within his own country, leading to his assassination in October 1981. Sadat's successor, Hosni Mubarak, continued Sadat's move toward more open economic policies and, with some reluctance, toward privatization and free markets. He also restored Egypt's relations with other Arab countries. Despite some further tentative steps toward democratization, the country remains firmly under presidential control.

The challenges that confront Egypt in the early twenty-first century involve many of the most pressing issues confronting the world today. Egypt has serious demographic concerns. Cairo is the largest city on the African continent, with a population of more than 16 million people, and the entire country contains over 80 million inhabitants with a high rate of increase. Like many other countries, Egypt must also worry about energy, although it has some oil and extensive natural gas fields. Water may prove to be the worst problem of all, as demands upon the Nile approach the river's maximum capacity. Egypt,

which contributes nothing to the river's supply, yet uses most of the water, will have to share with increasingly water-hungry nations upstream. Also, in a break with millennia of historical precedent, Egypt ceased to be a net food exporter in the mid-twentieth century and became a net food importer. The country can no longer feed itself, much less serve as a breadbasket to other nations. But the extraordinarily strong fabric of Egyptian society, which has withstood many stresses during the long millennia of its existence, will likely prove equal to these challenges as well as others that arise. Meanwhile the complex tapestries of its varied past, which have so often been interwoven with those of world events, will continue to enrich the human imagination.

Einstein, Albert

(1879–1955)

GERMAN-BORN SWISS-AMERICAN PHYSICIST

Albert Einstein remains one of the most influential people in the fields of science and mathematics. The Nobel Prize-winning physicist contributed theories on relativity and the photoelectric effect that are still upheld today. Though German born, Einstein lived out the last portion of his life in the United States and even urged President Roosevelt to act against Nazi Germany.

Albert Einstein contributed more than any other scientist to the twentieth-century vision of physical reality with his special and general theories of relativity, and he won the Nobel Prize for Physics in 1921 for his explanation of the photoelectric effect. Recognized in his own lifetime as one of the most brilliant minds in human history, he advanced a series of theories that proposed entirely new ways of thinking about space, time, and gravitation. His theories profoundly advanced the field of physics and revolutionized scientific and philosophical inquiry.

Born 14 March 1879, in Ulm, Germany, Einstein and his family moved a year later to Munich to establish a small electrical engineering firm as the family business. Einstein showed little interest or ability in school. Two of his uncles who were involved with the family business, however, stimulated his interest in mathematics and science. When the business failed in 1894, the family moved to Milan, Italy, and Einstein soon followed and then resumed his education in Switzerland. He graduated from the Zurich Polytechnic school in 1900 as a secondary school teacher of mathematics and physics, also becoming a Swiss citizen.

After a short period, he obtained a job as an examiner at the Swiss patent office in Bern and married his

Portrait of a young Albert Einstein. Photo by Rose Weiser.

university sweetheart, Mileva Maric, in 1903. They had two sons, but the marriage ended several years later. He married Elsa Lowenthal in 1919.

From 1902 to 1909, while working at the patent office, he completed an astonishing range of publications in theoretical physics. For the most part these

Philippe Halsman, *Albert Einstein* (1947). Gelatin silver print. The famous physicist as immortalized by the famous photographer. Halsman Photographic Company.

texts were written in his spare time and without the benefit of close contact with either scientific literature or theoretician colleagues. The publication of one paper, “A New Determination of Molecular Dimensions,” and its submission to the University of Zurich won him a doctoral degree in 1905. Einstein’s paper provided convincing evidence for the physical existence of atom-sized molecules, a much-theorized topic. In 1908 he sent a second paper to the University of Bern, which got him a job there as a lecturer. The next year he received an appointment as associate professor of physics at the University of Zurich.

One paper, on the production and transformation of light, revolutionized the theory of light. Still another, containing his special theory of relativity, had its beginnings in an essay he had written at age sixteen. The theory postulated that if, for all frames of reference, the speed of light is constant, and if all natural laws are the same, then both time and

motion are relative to the observer. The follow-up paper, “Does the Inertia of a Body Depend upon Its Energy Content?” established the equivalence of mass and energy, commonly expressed in the formula $E = mc^2$. The theory remained controversial for many years before its mainstream acceptance.

This outpouring of brilliance in such a short time made Einstein the leading scientific thinker among Europe’s physics community, though public understanding of his theories was years away. After moving quickly from one university post to another, in 1914 he became professor at the prestigious Prussian Academy of Science in Berlin. He occasionally lectured at the University of Berlin, but from this time on he never again taught regular university courses. He remained there until 1933, when the rise of fascism in Germany impelled him to leave for an analogous research position in the United States, at the Institute for Advanced Study in Princeton, New Jersey, a position he held until his death.

In his work after 1905, Einstein had made important contributions to the quantum theory, but increasingly thereafter he focused on perfecting his theory of relativity. By 1916, he had completed his general theory of relativity. It claimed that gravitation is not a force, as Isaac Newton had said, but a curved field in the space–time continuum created by the presence of a mass, such as the sun. When the theory was later proved during a solar eclipse, when his light-deflection prediction could be tested, the popular press praised Einstein.

Einstein’s stand as a pacifist who did not support Germany’s war aims brought him much respect outside Germany, but derision as a traitor and defeatist from his former countrymen. After World War I, when the victorious powers sought to exclude German scientists from international meetings, Einstein worked to include German physicists. His popularity and his political stances, which also included Zionism, led to attacks in the 1920s by anti-Semitic physicists. This in part explains why his Nobel Prize in 1921 was awarded not for relativity, but for his less controversial 1905 work on the photoelectric effect.

Only two things are infinite, the universe and human stupidity, and I'm not sure about the former. • **Albert Einstein (1879–1955)**

Einstein abandoned his pacifism when he realized that Hitler and the Nazis had to be stopped by military means, but he never stopped working on behalf of peace. Einstein sent a letter to President Franklin D. Roosevelt in 1939 urging that the United States develop an atomic bomb before Germany could do so. The letter contributed to Roosevelt's decision to fund what became the Manhattan Project. It is one of the great ironies of the pacifist Einstein's life that his energy–mass equation, which asserted that a particle of matter can be converted into an enormous quantity of energy, found its proof in the atomic and hydrogen bombs, the most destructive weapons ever created. After the war, he joined with other scientists in seeking to contain nuclear proliferation.

Though he failed in his political efforts, Einstein was not disappointed. His central interest always remained physics and the search to find the mathematical relationship between electromagnetism and gravitation, better known as the unified field theory. A version of the unified field theory he published in 1950 was politely criticized as flawed and went somewhat neglected for decades. In more recent years, physicists have begun trying to combine Einstein's relativity theory with quantum theory to arrive at a "theory of everything," by means of highly advanced

mathematical models. That some of Einstein's theories are only now being fully understood, decades after his death, stands as a testament to his place in science and human history.

Electricity

Although the word *electric* was first introduced in the sixteenth century, it wasn't until after the Scientific Revolution of the eighteenth century that serious investigation of electricity began. Scientists worldwide experimented with electricity, and in the nineteenth century society recognized the usefulness of electric power. The current human reliance on electricity calls for a need to research alternative forms of power for the future.

Electricity is so common today that it would be difficult for anyone to imagine how life would be without the well-known applications we use every day in our homes and jobs. But things were not always that way. It is just four hundred years since scientists began to study electrical phenomena and the nature of electricity, and no more than 150 years since electrical applications started to be a part of our way of living.

Around 600 BCE, one of the natural philosophers of ancient Greece, Thales of Miletus (c. 625–547? BCE), observed that rubbing amber against a piece of cloth attracted light bodies. This remained the only reference to an electrical phenomenon for almost two thousand years, and though it was considered quite impressive, the cause of this strange effect remained unexplained.

At the end of the sixteenth century, the Englishman William Gilbert (1540–1603) became the godfather of electricity, as he was the first natural philosopher who introduced the word *electric*, in his book *De Magnete*.

The Eighteenth Century

A more systematic investigation of electrical phenomena took place during the course of the eighteenth century, following the scientific revolution.

Stephen Gray (1667–1736) in England and Charles Francois de Cisternay DuFay (1698–1739) in France worked seriously on electricity. Gray in 1732 demonstrated electrical conductivity. A decade later, in 1745, the Dutch physicist Peter van Musschenbroek (1692–1761), the most important popularizer of Newtonian physics, invented the first kind of electrical condenser, the Leyden jar. (Some argue, however, that the real inventor of the Leyden jar was Ewald Jurgen von Kleist, in Kammin, Pomerania.)

The years to come were very productive with regard to electricity. Electrical experiments, especially those using electrostatic machines, became very popular. Scientists performed experimental demonstrations using static electrical charges in the salons of the French and Italian nobility and the courts of the European kings. The audience sometimes participated actively in these experiments, and their fascination with the impressive results can be seen in engravings of the period. One example is the experiment performed by the French physicist Pierre Charles Le Monnier (1715–1799) in the court of the king in order to prove the strength of an electric shock caused by a Leyden jar—a test in which 140 people participated.

Around 1750 there were two leading figures investigating electricity: Abbé Nollet (1700–1750) in France and Benjamin Franklin (1706–1790) on the other side of the Atlantic Ocean. They proposed two different theories of electricity, and a strong debate started in

the scientific community. Nollet devoted himself to the study of electricity, and his theory, presented in his book *Essai sur l'électricité des corps* (Essay on the electricity of the bodies) (1746), can be summarized by the proposition that electrical matter is a combination of elementary fire and denser matter.

According to Benjamin Franklin's biographers he first became engaged with electricity following his astonishment at some spectacular electrical demonstrations performed by Dr. Archibald Spencer in Boston in 1743. Today Franklin is mostly known for his experiment with kites, intended to demonstrate that lightning is a form of static electricity. But his work on the nature of electric matter is much more fundamental from a scientific point of view. He was the first to propose, in contrast to previous theories, that electricity was a single common element, or fluid, passing through all matter (the "single-fluid" theory), and that it had no weight. Differences in electrical charge were caused by an excess (+) or deficiency (−) of this fluid.

As Franklin's theory gradually came to prevail during the last quarter of the eighteenth century, two new thinkers contributed to the development of the theoretical and experimental concept of electricity. In 1785, Charles August Coulomb (1736–1806) used the torsion balance to find the inverse square law governing the electrical force between two charges. In 1791 the Italian Luigi Galvani (1737–1798) conducted a well-known experiment with a frog's leg to prove that there was a relationship between living beings and electricity. Galvani's conclusions were proved wrong some years later by his rival in the scientific field, Alessandro Volta (1745–1827).

The Nineteenth Century

During the nineteenth century there was dramatic progress in the study of electrical phenomena. In 1800 Alessandro Volta, a professor at the University of Pavia in Italy, created the so-called voltaic pile, the first battery, opening new horizons to electrical applications. For the first time the general public, and scientists

Volta's voltaic pile, the first battery for producing a current of electricity, consists of alternating disks of different metals, such as copper and zinc, which are separated by flannel or pasteboard moistened with salt water or a dilution of sulfuric acid.

in particular, had steady and reliable access to an electrical current over an extended period of time.

The Danish physicist Hans Christian Oersted (1777–1851) found that electrical current would deflect a magnetic needle, thus establishing the discipline of electromagnetism. The basic mathematical equations of electromagnetism were developed by André-Marie Ampère (1775–1836) in 1820s.

In 1826 Georg Simon Ohm (1787–1854) proposed the law defining the resistance of metallic conductors. During the same decade Michael Faraday (1791–1867) impelled electromagnetism even further by building the first electric motor, transforming electric energy to kinetic energy. In addition, Faraday's theoretical proposal about dynamic lines provided a foundation for the Scotsman James Clerk Maxwell (1831–1879), who in 1856 wrote the essay "On Faraday's Lines of Force," establishing in pure mathematical language the new subject of field physics, unifying magnetism, electricity, and light. Maxwell's laws of electrodynamics were important for the development of many useful applications during the twentieth century like electric power stations, radio, television, and even the computer.

But before these applications came the electric telegraph, invented by Samuel Morse (1791–1872) around 1840, which caused a real revolution in

A close-up of a turbine generator in the Ruacana Hydroelectric Power Station, Namibia.

communications. After Morse, Thomas Edison (1847–1931) became famous for his electric lamp, not to mention his many other inventions, like the phonograph. Carbon arc lamps were used around the world extensively until the late 1970s, but the invention of the incandescent filament lamp by the Englishman Joseph Swan (1828–1914) in 1878 and by Thomas Edison in 1879 in the United States reduced their use dramatically in the years to follow.

As the usefulness of electricity was recognized by society, the need for electric power started to become immense. Carbon, oil, and waterfalls became the main sources for the energy needed. In 1896 George Westinghouse (1846–1914) used Niagara Falls to produce electric power and transmit it to cities like New York. Westinghouse collaborated closely with the Serbian physicist Nicola Tesla (1856–1943) in the development of an electrification system based on alternating current (AC). This advance led to long discussions with the supporters of direct current (DC) like Edison, but finally alternating current prevailed.

The Twentieth Century

During the twentieth century the use of electricity became fundamental in the lives of Western societies, but it is no less important for the developing world. The continuous increase in the need for electricity led to the establishment of nuclear-powered electric stations and the establishment of huge dams

to collect the necessary quantity of water for use in hydroelectric plants. One of them, for example, the Aswan High Dam in Egypt, changed the whole economic and social profile of the country. During the last decades of the twentieth century alternative sources for the production of electricity became more popular. Among them, solar energy and wind energy are the most widely used. In countries with high tides like England and France, these are also used for the production of electricity.

There is no doubt that civilization as we know it could not exist without electricity, yet we must not forget that electricity is a product of that civilization. Therefore, it is necessary for people to secure the use of electric energy in the future by constructing the necessary factories and networks, having always in mind that oil and carbon will not last forever, and that sun, water, and air can provide cheaper and more environmentally friendly sources for the power supply we need.

Queen Elizabeth I posed in coronation robes patterned with Tudor roses and trimmed with ermine. Unknown artist, circa 1600, painted after a lost original. National Portrait Gallery, London.

talk directly with ambassadors from many countries, and this fact ensured that no information could be lost in translation. Cecil's admiration for her grasp of policy and politics is evident in his remark that "there never was so wise a woman born, for all respects, as Queen Elizabeth, for she spake and understood all languages; knew all estates and dispositions of Princes. And particularly was so expert in the knowledge of her own realm and estate as no counsellor she had could tell her what she knew not before" (Somerset 1997, 64).

Although Elizabeth never traveled beyond England, she was not an insular queen. Indeed, she was an expert on foreign policy, and one of her legacies was the establishment of England as a maritime nation. Although she never formally condoned piracy on the high seas, Elizabeth informally encouraged (partly through financing) Francis Drake and other sailors to plunder on her behalf. During her reign English merchant ships challenged Spain's seafaring

preeminence, and the first English settlers were sent to North America.

Elizabeth was pragmatic about international affairs. Careful with money, she was reluctant to fight wars because their cost inevitably drained her treasury. She also appreciated the necessity of managing her reputation. Her courtiers frequently used propaganda and "political spin" on her behalf. In matters of international politics monarchs were always aware of their image. Their status within the international arena also reflected directly on their courtiers, especially ambassadors in foreign courts—prestige by association. As a woman, Elizabeth was at a disadvantage within the international hierarchy; however, her intellect, judgment, and grasp of foreign policy became legendary. Consequently, as her reign proceeded, the reputation of both Elizabeth and of England grew. Visual images of Elizabeth were also tightly controlled. Paintings presented her as a powerful ruler and cultivated her image as a forever youthful virgin queen who was married to England and her subjects. Elizabeth used her travels around the country to make herself visible to her subjects. Her courtiers were often amazed at how she allowed the common people to approach her.

Religious divisions were a major issue throughout Elizabeth's reign. Her father, Henry VIII, had rebelled against the pope and rejected the Catholic Church, which dominated Europe. Subsequently, Queen Mary, Elizabeth's half-sister, had returned England to Catholicism and married Philip II, the Catholic king of Spain. Mary had persecuted people who had resisted the Catholic religion. Elizabeth was aware of the religious polarities within England and was more tolerant. Although she returned her country to Protestantism, Elizabeth recognized the dangers of encouraging the extremist elements of Protestantism. She insisted on changes in church services but retained many of the trappings of Catholic worship, such as crucifixes, clerical robes, and candlesticks.

Taking a religious middle ground, Elizabeth brought a degree of peace to England—peace that was not found in continental Europe, where religious

Marcus Gheeraerts the Younger, *Queen Elizabeth I* (c. 1592). Oil on panel. Elizabeth learned survival skills at an early age, and they served her throughout her life.

fanaticism and turbulence were rife. The Inquisition terrorized Spain, and in France heretics were burned at the stake. By contrast, Elizabeth attempted to defuse religious tensions by increasing outward compliance with Protestant services. Any person who did not attend church was subject to a fine. But during the first part of Elizabeth's reign Catholics who either attended the parish church or paid their fines for nonattendance could usually still practice their religion privately without fear of persecution. In contrast to Elizabeth's more lenient attitude in religious matters, her counselors feared that Catholic religious extremists would assassinate the queen. Francis Walsingham (c. 1532–1590), acting under the direction of Cecil, was in charge of gathering information about any threats to the queen through a network of spies. Walsingham, who held extreme Puritan views, operated a counterespionage organization that used double agents and torture to obtain information. Although Elizabeth considered Walsingham to be an extremist in terms of religion, she admired his shrewdness and never doubted his devotion to her welfare.

Elizabeth's religious moderation was tested when her cousin Mary, Queen of Scots (1542–1587) took sanctuary in England in 1568 after an uprising in Scotland. Mary was Catholic, and some Catholic factions at the national and international level believed that she was the rightful queen of England. Cecil and Walsingham were concerned that Mary's presence in England posed a threat to Elizabeth's safety. After almost twenty years in captivity in England, Mary was executed for treason in 1587.

Like many leaders, Queen Elizabeth had a strong sense of destiny: she had no doubt that her rise to the throne was the will of God. When informed that her half-sister Mary Tudor had died and that Elizabeth was now queen, Elizabeth stated, "This is the Lord's doing; and it is marvelous in our eyes" (Marshall 1991, 47). Elizabeth viewed the advantages that accrued from her sovereign status as far outweighing the disadvantages that accrued from her gender. For Elizabeth being a woman was more an irrelevance than a handicap, stating that "my sex cannot diminish my prestige" (Somerset 1997, 60).

During the sixteenth century the first duty of a monarch was to marry and have children, thereby ensuring the succession of the throne. Cecil in particular was eager to secure the succession and create a Protestant heir to the throne. As queen, Elizabeth was expected to marry someone of royal blood. She understood that marriage to a foreign prince offered some security from hostile nations in Europe, but she also understood that the English people were antagonistic toward foreigners. Mary Tudor's marriage to King Philip II of Spain had caused great disruption within England. Elizabeth's other option was marriage to an English nobleman. She thought, however, that such a marriage would create jealousies within the nobility and could lead even to civil war. To her, having to share power with a husband conflicted with her sense of personal destiny. Elizabeth's childhood experiences and her knowledge of international politics had led her to believe that marriage would be disadvantageous both to her and to her realm. Although an unmarried queen was considered unnatural at

that time, Elizabeth turned her single status into a strength.

Elizabeth's policy of remaining single did leave the problem of succession. The loss of such a charismatic leader as Queen Elizabeth left a vacuum in England that resulted in great internal conflict. On her death she was succeeded by the son of Mary, Queen of Scots, James I of England (1566–1625; reigned as James VI of Scotland 1567–1625 and as king of England 1603–1625), who had been raised a Protestant. This subsequent period in English history was one of social turmoil, religious strife, and civil war.

Elizabeth was an extraordinary woman, respected abroad and celebrated at home. Four hundred years after her death we still recognize her legacy as one of the greatest monarchs in English history. Her reign brought increasing prosperity and peace and strengthened England's international interests. After the turbulent years of Henry VIII's reign, the relative stability that England enjoyed during Elizabeth's reign advanced the development of English culture. Her reign led to the emergence of the mighty British Empire. In North America, Virginia (named after Elizabeth, the Virgin Queen) was explored and colonized. England defeated the Spanish Armada and became a dominant sea power. Drake circumnavigated the globe. Sailors such as Raleigh and Drake took the English language abroad; today it has become the language of world communication. Her policies encouraged development of parliamentary democracy, a moderate Church of England, and, for her time, a relatively prosperous, peaceful, and stable society. Many scholars consider the Elizabethan era to have been a golden age. Indeed, Elizabeth came to be known as "Gloriana," a name that reflected the triumphs of her reign.

Empire

One of the most commonly used terms in world history, *empire* appears in reference to a long list of powerful states and societies, ranging from the ancient Akkadians to contemporary America. Many of the leading themes in world history—war, migration, trade, globalization—arose in conjunction with empires, which acted as crucial engines of change and touched the lives of immense numbers of peoples.

Dominic Lieven, a scholar of Russian government, has observed: “To write the history of empire would be close to writing the history of mankind” (2002, xiii). The very pervasiveness of *empire* as a historical category makes its meaning difficult to pin down. Definitions abound. Typologies proliferate. The term is often used interchangeably with *dynasty* and *civilization*. While most historians are likely to agree that *empire* refers to the political power exerted by a state or its agents over a culturally diverse group of peoples, this understanding of the term is so vague as to accommodate any number of different historical phenomena, ranging from the continental-wide conquests of the Mongols to the transoceanic extortions of the Portuguese. Moreover, even this definition may not be broad enough to account for the meaning of *empire* associated, for example, with the Holy Roman Empire, a loose affiliation of central European states that shared a common allegiance to the Catholic faith. In the end, *empire* can be seen a kind of palimpsest on which historians have written about various subjects associated with the consolidation of communities into large political units.

Etymology and Uses

The term *empire* derives from the Latin *imperium*, which originally meant the sovereignty held by a magistrate, but later evolved to refer to the authority that the ancient Romans established over much of Europe and the Near East. Its etymology indicates the main source and standard for its usage. The Roman Empire became the archetype of what an empire should look like and how it should behave, a positive model for the Europeans who sought to emulate its achievements. In the east, the Byzantine Empire kept its heritage alive for nearly a millennium. In the west, the Carolingian Empire, the Napoleonic Empire, the British Empire, Hitler’s Third Reich, and various other expansionist European states consciously evoked the Roman Empire in their iconography and ideological claims to legitimacy. The Roman model made its mark on European historiography as well, acquiring a prominent place in literature that sought to discern the patterns of history and distill its lessons. Edward Gibbon’s *Decline and Fall of the Roman Empire* (1776–1788) is arguably the most influential work of history ever written.

Empire also carries negative connotations, evoking charges of political and cultural oppression. This use of the term has its origins in the classical Mediterranean world as well, though its principle source is probably the Achaemenid Empire of Persia, which threatened the independence of the Greeks. The same connotations are attached in Western historiography to its successors, the Sasinid and Safavid empires, as well as to neighboring states that came in collision with Europe, notably the Ottoman and

The terracotta warriors of China's Qin dynasty were sculpted circa 210 BCE to guard the Emperor Shi Huangdi's tomb. Photo by Chris Howell.

Mughal empires. The term is used less consistently in other geographical and historical contexts. While the closest counterpart to the Roman Empire was in many respects the contemporaneous Han polity of China, it is more often called a dynasty than an empire. The same is true for its successor states—the Tang, the Song, the Ming, the Qing, and others.

Some historians have shown similar reservations about using the term *empire* in reference to the Abbasids and Umayyads, who consolidated political authority across much of the Near East and North Africa under the banner of Islam. In sub-Saharan Africa, indigenous polities rarely receive the appellation empire, the main exceptions being the West African states of Ghana, Mali, and Songhai, whose indirect association with medieval Europe gave them mythic reputations. Similarly, the only polities in the Americas commonly characterized as empires are those that fell to Spanish conquerors, the Aztecs and the Incas, even though archeologists have determined the earlier existence of other large states in the same locations and in other parts in the Western Hemisphere. The ambivalence and inconsistency that have characterized the use of *empire* serve as a reminder that words and their meanings are no less embedded in the particularities of history than other aspects of human experience.

Empire Building as State Building

For all the semantic uncertainty surrounding the term *empire*, there can be little doubt that the phenomenon

it signifies was a consequence of the rise of states. Empires appeared on the scene soon after the first states came into existence in the densely populated river valleys of Mesopotamia, Egypt, China, and elsewhere. Indeed, the association between the two is so close that it is not entirely clear when state building becomes empire building. Every successful state soon expanded its reach well beyond the real or fictive lineage ties and ethnic bonds that supplied its original claims of sovereignty, relying on conquest and other coercive methods to bring additional peoples under its control. The demands for labor and tribute, the reliance on armies and bureaucracies, and the insistence on hierarchy and hereditary privilege were common to both types of polities. As David Armitage has stated, “Empires gave birth to states, and states stood at the heart of empires” (2000, 15).

The distinction most often drawn between empires and other states can be characterized as functions of intent and degree: empires are those states that seemed especially aggressive in their expansionist ambitions and especially accomplished at extending their sway over other peoples. Yet the same state could fluctuate quite dramatically in terms of the policies it pursued and the territories it controlled, thus exhibiting more or fewer of the characteristics of an empire as its aims and fortunes varied. It is impossible, for example, to know how to classify Pharaonic Egypt, which expanded and contracted repeatedly over the course of its long history, conquering others and being conquered in turn. Part of the problem derives from the fact that we tend to look at the intentions and actions of individual states to determine whether or when they were empires, whereas it was their “spheres of interaction” with neighboring peoples that often determined this outcome (Alcock et al. 2001, 40).

In modern times, the rise of the nation-state presents what seems at first sight a much clearer typological contrast to empire, since its reliance on linguistic and/or ethnic homogeneity and the claim of popular sovereignty stand at odds with the foundational premises of empire. Yet archetypal nation-states like Britain and France established huge empires that stretched

This illustration from a 1914 children's magazine is entitled "Round the World with the Union Jack." It supports the notion of empire with the European explorer sitting casually as he talks to the African leader.

around the globe. They resolved the apparent contradiction between their dual roles as nation-states and empires by maintaining strict institutional and ideological boundaries between the metropolitan sphere, where the principles of the nation-state applied, and the overseas possessions, where they did not.

Land-Based Empires

The vast majority of empires until the last four or five hundred years consisted of states that extended their power into contiguous territory, either through conquest or composite monarchy. A key dynamic in the rise and fall of these land-based empires was the sometimes complementary, sometimes adversarial relationship between the sedentary agricultural societies that gave rise to states and the pastoralists and other mobile peoples who operated outside the

boundaries of those states. The two groups usually kept their distance from one another, coming together mainly to trade goods, but environmental changes, demographic pressures, and other forces provoked periodic clashes between them. States and their agrarian populations enjoyed the advantages of concentration, central direction, and sheer numbers over their widely dispersed, frequently fissiparous adversaries, and their demand for land, labor, and tribute gave them motive to encroach on the domains of the latter.

Even when states merely sought to secure their frontiers against raids by nomads, their efforts often sucked them further and further into the hinterland in an unending quest for security. Given the right circumstances, these dynamics could lead them to absorb an immense amount of territory: two classic examples are the Roman and Han empires. The significance

It is yet another Civilized Power, with its banner of the Prince of Peace in one hand and its loot-basket and its butcher-knife in the other. • **Mark Twain (1835–1910)**

that these empires attached to their troubled relations with pastoralists and other unpacified peoples is evident in the way they represented themselves and their actions as advancing the cause of “civilization” against the “barbarians” on their borders. One of the standard tropes of empire would become this dichotomy between civilization and barbarism.

Pastoralists were by no means the mere victims of empires, however. A perennial theme of world history is the sudden breakout by nomadic invaders whose mobility, weaponry, and warrior ethos overwhelmed sedentary agricultural societies. These events had several quite different outcomes. One was the destruction of the conquered state and the fragmentation of political authority. Examples include western Europe after the fall of Rome in the fifth century CE and West Africa after the invasion of Songhai in 1591 CE. In other instances, the “barbarian” invaders preserved the lineaments of the state, but placed themselves at its head. Although they ran the risk of cultural absorption by the host society, they also gained access to its immense resources, which they were able to mobilize to carry out still more conquests. Two of the largest empires in Eurasian history were the work of pastoralist peoples, the Mongols and the Arabs. Both burst out of their natal lands (the Central Asian steppes and the Arabian desert), crushed the states that stood against them, created new state structures on the foundations of the old, and used them in the task of empire building with astonishing success.

After about 1450 CE, however, the pastoralist threat to agrarian societies began to disappear. As William H. McNeill and others have argued, the gunpowder weapons that came on the scene around this time proved to be more than a match for nomadic warriors on horseback. They gave an irreversible strategic advantage to large sedentary states, which had the fiscal, technical, and logistical means to produce these weapons on a large scale and put them into use with devastating effect. The result was the rise of new gunpowder empires in Europe, Russia, China, India, and the Near East which hemmed in their nomadic neighbors and put an end forever to their depredations on agricultural communities.

Transoceanic Empires

The mid-fifteenth century marked a related shift in the history of empires—the rise of western European transoceanic empires. The projection of power by sea was not in itself a new phenomenon. The Greeks and the Phoenicians had used their seafaring skills to plant their peoples and spread their influence across the ancient Mediterranean world, though neither found a way to knit their scattered communities together into a single powerful state. The Vikings faced the same problem despite their remarkable success in raiding and settling coastal zones from the North Sea to the Mediterranean. The Persian Gulf, Indian Ocean, and the South China Sea all sustained their own series of seaborne traders and raiders, some of whom established polities of considerable size and sophistication. By sitting astride the Malaccan Strait, a chokepoint in the Asian seaborne trade, Srivijaya became the dominant power in Southeast Asia in the seventh century. Oman, a small city-state on the southern Arabian coast, controlled trade along the east coast of Africa through much of the eighteenth and nineteenth centuries. In the estimation of some historians, both states became empires.

The transoceanic empires established by western European states shared some features with the cases mentioned above, but they differed in crucial respects as well. Like most of their sea-borne predecessors, they set out in search of trade, not of the tribute that sustained land-based empires. Trade would remain an integral feature of these empires, so much so that many theorists and historians have concluded that modern European imperialism was driven first and foremost by the demands of commerce and capitalism. But western European states also established the sort of centralized political control over their overseas possessions that was more characteristic of land-based empires than of previous seaborne polities. This can be explained in part by the fact that they were at the forefront of the military revolution precipitated by gunpowder weaponry, allowing them to exercise power over greater distances than ever before. Above all, however, it was due to the contemporaneous consolidation

Fortifications have been a key component of empire building. El Morro, built by the Spanish in San Juan, Puerto Rico, has been maintained as a tourist attraction and educational facility.

of strong centralized states at home, which provided the incentives—and the blueprints—for the extension of these policies and institutions abroad.

Portugal, the earliest and least developed of the European states that sought an overseas empire, had the least success in establishing a political foothold in foreign lands. Its larger and more powerful neighbor, Spain, effected a far greater transformation on the territories it claimed. And although France, England, Holland, and other European states each had its own distinct imperial style, all of them sought to subordinate the colonies they established to the political will of the metropolis.

Most historians agree that these European overseas empires had an unprecedented effect on world history. By bringing together parts of the world that had been effectively isolated from one another since the dawn of civilization, they set in motion a series of changes that rippled around the globe. They brought about a transfer of diseases, plants, and animals that transformed environments and societies almost everywhere. One of the most immediate consequences was the sharp

reduction of indigenous populations in the Americas, Australia, and other regions where the arrival of deadly new microbes generated “virgin soil” epidemics, while over the long term the spread of new food crops supported an unparalleled growth in the world’s population. European overseas empires also facilitated the transfer of peoples from one continent to another.

Streams of emigrants from Europe settled in North America, Australia, New Zealand, and other mainly temperate lands, laying the foundations for what Alfred Crosby has aptly termed “neo-Europes.” At the same time, millions of Africans were sent as slaves to New World plantations, while large numbers of indentured servants from India, China, and other lands sailed across the seas to meet the labor demands of European-owned economic enterprises. These enterprises were integral to the global transfer of goods that also distinguished the transoceanic empires of western European states. By orchestrating the operations of this system, Europeans became its main beneficiaries. This was especially true after industrialization at home skewed the terms of trade in favor of European manufactured

goods, creating a growing disparity of wealth between Europe and much of the rest of the world. Although the United States, Japan, and other countries worked their way into the column of industrialized countries, the fissure between rich and poor peoples remains a lasting legacy of European overseas empires.

Ideologies of Empire

While the drive for power and wealth may have been the basic motive behind imperial expansion, no empire lasted very long if it didn't develop an ideological claim on behalf of its own legitimacy. Quite apart from inspiring the empire's agents or easing their consciences, this claim sought to make conquered peoples more acquiescent to their own subjugation. The key to accomplishing this goal was the dissemination of an idea or doctrine that overcame ethnic or cultural particularisms, offering in their stead integration into a larger imperial identity. The Romans were famous for their promise of citizenship under Roman law. The Han and their successors embraced Confucian principles and perpetuated them through the efforts of a relatively open bureaucratic elite. Although rulers also relied on religion to bolster their authority, they ran the risk that their official faith would alienate subject peoples who worshipped different gods. Most empires took care to respect religious diversity.

The relationship between empire and religion did, however, undergo a significant shift with the emergence of Christianity and then Islam. Both were universalist creeds that welcomed all converts, irrespective of their origins. This made them attractive to empires seeking ways to incorporate newly conquered subjects; by the same token, empires were attractive to them as instruments for the propagation of the faith. Though forced conversions were uncommon and counterproductive, both Christianity and Islam often worked hand-in-glove with empires, supplying them with important ideological rationales for their rule.

Christianity was integral to the early modern European empires, which found especially fertile grounds for their missionary endeavors among the demoralized and much diminished peoples of the Americas and the

deracinated slaves shipped from Africa. Once they came into possession of large tracts of South and Southeast Asian territory in the late eighteenth century, however, they had to develop alternative justifications for their presence, since Christianity simply antagonized the region's Hindu, Muslim, and Buddhist populations. The introduction of stable government and the rule of law, the promotion of prosperity through international trade, the advancement of scientific knowledge and its application in modern medicine and technology, and various other claims were made in justification of European imperial rule. Underlying all of these claims was the assertion that empire brought the benefits of civilization to colonial subjects. Whether expressed in secular or religious terms, a belief in the superiority of its own way of life—what it characterized as civilization—lay at the ideological heart of every empire.

Costs, Benefits, Consequences

Whether for good or ill, empires were crucial engines of change in world history. They were the paramount institutional expressions of the human will to power, exerting greater authority over greater numbers of people than any other system of rule. Their armies and ambitions caused untold human suffering and destruction. At the same time, they brought culturally diverse and geographically scattered peoples together, providing the political framework for the rise of those large, vigorous societies that often go by the name of civilizations. They also served as the nurseries for the acquisition of skills, the invention of products, and the origination of ideas that spread far beyond the physical boundaries and the temporal existence of the empires themselves. Lastly, their relentless drive for expansion supplied much of the impetus for those ever-enlarging systems of interaction and exchange that eventuated in what we now know as globalization, with all its attractions and drawbacks.

Energy

From simple mechanical muscle energy to the energy derived from radioactive materials, energy use has ebbed and flowed throughout history. The economic, social, and political consequences of these changes are great, correlating with the rise and fall of empires and eras. Energy use continues to evolve in tandem with humanity and will dictate which choices are available for future development.

When seen from the most fundamental physical point of view, all processes—natural or social, geological or historical, gradual or sudden—are just conversions of energy that must conform to the laws of thermodynamics as such conversions increase the overall entropy (the degree of disorder or uncertainty) of the universe. This perspective would make the possession and mastery of energy resources and their ingenious use the critical factor shaping human affairs. Also, given the progressively higher use of energy in major civilizations, this perspective would lead logically to a notion of linear advances with history reduced to a quest for increased complexity that is made possible by higher energy flows. People who could command—and societies and civilizations who could use large or high-quality energy resources with superior intensities or efficiencies—would be obvious thermodynamic winners; those converting less with lower efficiencies would be fundamentally disadvantaged.

Such a deterministic interpretation of energy's role in world history may be a flawless proposition in terms of fundamental physics, but it amounts to a historically untenable reductionism (explanation of complex life-science processes and phenomena in terms of the

laws of physics and chemistry) of vastly more complex realities. Energy sources and their conversions do not determine a society's aspirations, its ethos (distinguishing character, sentiment, moral nature, or guiding beliefs) and cohesion, its fundamental cultural accomplishments, its long-term resilience or fragility.

Nicholas Georgescu-Roegen, a pioneer of thermodynamic studies of economy and the environment, made a similar point in 1980 by emphasizing that such physical fundamentals are akin to geometric constraints on the size of the diagonals in a square—but they do not determine its color and tell us nothing whatsoever about how that color came about. Analogically, all societies have their overall scope of action, their technical and economic capacities, and their social achievements constrained by the kinds of energy sources and by varieties and efficiencies of prime movers that they rely on—but these constraints cannot explain such critical cultural factors as creative brilliance or religious fervor, and they offer little predictive guidance regarding a society's form and efficiency of governance or its dedication to the welfare of its citizens. The best explanation of energy's role in history thus calls for a difficult task of balancing these two realities, of striving for explanations that take account of these opposites.

Periodization based on the dominant uses of primary energy cleaves world history into just two highly asymmetrical spans: the renewable fuel era and the nonrenewable fuel era. All premodern societies relied overwhelmingly on solar, that is, perpetually (when measured on civilizational time scales) renewable energies. They derived their heat and light from biomass (the amount of living matter) that is produced by

This diagram shows the primary mechanical parts of the upper portion of a windmill.

photosynthetic conversion of sunlight and harvested mostly as wood and crop residues, above all straws and stalks; plant and animal fats were also used in lighting. Their kinetic energy came from human and animal metabolism (energized, obviously, by eating the biomass) and, to a much lesser extent, from wind and flowing water, the two forms of converted solar radiation (after it is absorbed by the Earth's biosphere) that power the global water cycle and atmospheric circulation.

Fossil fuels, too, had their origin in photosynthesis, but the constituent biomass was subsequently transformed into qualitatively new materials over a period of 1 million to 100 million years by high temperatures and pressures in the uppermost layers of the Earth's crust. Consequently, fossil fuels—ranging, in the ascending order of quality, from peats through various coals (lignites to anthracites) to hydrocarbons (crude oils and natural gases)—are not renewable on historic time scales. This means that premodern, solar societies had an energy basis whose potential longevity coincided with the remaining duration of the biosphere (the part of the world in which life can exist) itself (i.e., still hundreds of millions of years to go). On the other hand, modern societies will have to change their energy base if they are to survive for more than a few hundred years.

Biomass Fuels

Biomass fuels had two inherent disadvantages: low power density (expressed in watts per square meter— W/m^2) and low energy density (expressed in joules per kilogram— J/kg). Even in rich forests biomass was harvested with densities not surpassing 1 W/m^2 , but most people did not have tools to cut mature tree trunks and had to rely on smaller trees, branches, and leaves gathered with much lower density. Similarly, the collection of crop residues, needed also as feed and as a raw material, rarely yielded more than 0.1 W/m^2 . Consequently, extensive forested areas were needed in order to supply the energy needs of larger settlements. A large preindustrial city in a temperate climate would have required at least 20 to 30 watts (W) per square meter of its built-up area for heating, cooking, and manufacturing, and, depending on the kind fuel it used, it would have needed a nearby area of up to three hundred times its size to supply its fuel. The constraint is clear: no temperate-climate megacities of 10 million people or more could have existed during the era when wood was the main source of energy.

These power density limitations became even more acute after charcoal became used on a relatively large scale. Conversion from wood to charcoal was done to increase wood's low energy density: in its air-dried

Table 1.
Energy Densities of Common Fuels

Fuel	Density (MJ/kg)
Dried dung	10–12
Air-dried straw	14–16
Air-dried wood	15–17
Charcoal	28–29
Lignites	10–20
Bituminous coals	20–26
Anthracites	27–30
Crude oil	41–42
Gasoline	44–45
Natural gas (cubic meters)	33–37

This series of drawings shows the variety of means used to make fire over time and across cultures: (4) fire saw from Borneo; (5) fire thong from Borneo; (6) fire plow from Polynesia; (7) fire drill from Native America; (8) fire drill from Inuit of Alaska; (9) fire drill from Inuit of Alaska; (10) fire drill from Iroquois of Canada; (11) strike-a-light from Inuit of Alaska; (12) strike-a-light from England; (13) strike-a-light from Malaysia; (14) tinder pistol from England; (15) strike-a-light from Spain; (16) fire syringe from Thailand and Malaysia; (17) lens from ancient Greece; (18) hydrogen lamp from Germany; (19) match light box from Austria; (20) matches; (21) electric gas lighter from the United States.

form (about 20 percent moisture) the fuel had about 18 MJ/kg, whereas charcoal rates about 60 percent higher at 29 MJ/kg. The obvious advantages of the better fuel include smaller mass to be transported and stored, smaller furnaces (or braziers), less frequent stoking, and less air pollution. But traditional charcoaling was inefficient, wasting about 80 percent of the initially used wood in the process. This waste would put a great strain on wood resources even if charcoal's use was limited to space heating and cooking, but its expanded use in various manufactures and in metallurgy made it an acutely limiting factor. For example, in 1810 the metallurgical charcoal needs of

the United States prorated annually to a forested area of roughly 50 by 50 kilometers (2,500 square kilometers), and a century later they would have amounted to an area of 170,000 square kilometers, equal to a square whose side is the distance between Philadelphia and Boston. The constraint is clear: no global steel-dominated civilization based on charcoal could exist, and coal-derived coke took over.

Human and Animal Muscles

Similarly, the limited power of human and animal muscles constrained productive capacities as well as

Russell Lee, *Filling Station and Garage at Pie Town, New Mexico* (1940). Color slide. This photo is part of an iconic series commissioned by the Farm Security Administration to document life in the United States after the Depression. Library of Congress.

aggressive forays of all traditional societies. Healthy adults can sustain work at 40–50 percent of their maximum aerobic capacity, and for men (assuming muscle efficiencies of 20 percent) this translates to 70–100 W of useful work. Small bovines (cattle and water buffalo) can sustain about 300 W, lighter horses around 500 W, and heavier animals 800–900 W (one horsepower is equal to 745 W). These rates give common equivalences of at least four men for an ox and eight to ten men for a horse. No less importantly, heavier draft animals can develop briefly maximum power well in excess of 3 kilowatts (kW) and can thus perform tasks unattainable by men (plowing heavy soils, pulling out tree stumps). Larger numbers of stronger draft animals thus greatly improved the productivity of traditional farming: even slow plowing was three to five times faster than hoeing.

These gains, however, had to be paid for by devoting more time to caring for these animals and devoting increasing amounts of land to their feeding. For example, feeding the peak number of U.S. farm horses and mules in 1919 (approximately 25 million) required about 20 percent of the country's farmland. Obviously, only countries endowed with extensive farmland could afford this burden: the option was foreclosed for Japan, China, or India. Heavier draft animals and better implements eventually cut the time that was spent in producing staple crops. For example, all fieldwork on a hectare of wheat required

180 hours in medieval England, 120 hours in early nineteenth-century Holland, and 60 hours on the U.S. Great Plains in 1900. But in any society where food production was energized solely by human and animal muscles, most of the labor force had to be employed in agriculture. The rates ranged from more than 90 percent in imperial China to more than 66 percent in the post-Civil War United States, and in all traditional agricultures children commonly helped adults.

Limits were also obvious in warfare because even trained muscles could impart relatively restrained destructive force to the tools of war, a reality made clear by comparing kinetic energies of common pre-industrial weapons. The kinetic energy of a single stone ball shot from a medieval cannon equaled that of five hundred arrows discharged from heavy crossbows or one thousand thrusts delivered with heavy swords. Pregunpowder battles thus consisted of limited expenditures of muscular energy, a reality that explains frequent preference for either sieges or stealthy maneuvers. Wars became much more destructive only with the introduction of gunpowder—in China during the tenth century and in Europe at the beginning of the fourteenth century.

Speed of travel was another obvious constraint imposed by animate metabolism and by inefficient conversion of wind. Speedy running and horse

The water mill at *Tranquille Mills, Kamloops Lake, British Columbia, 1871*. Photo by Benjamin F. Baltzly. McCord Museum.

riding were used only for urgent messaging, and impressive distances could be covered in a single day: the maximum on Roman roads was up to 380 kilometers. Speeds of normal travel, however, were restricted to 10–15 kilometers a day for men with wheelbarrows (a common means of transport in imperial China), not much more for wagons drawn by oxen, 30–40 kilometers for wagons pulled by heavy horses, and 50–70 kilometers for passenger horse carts on relatively good roads. The prohibitive costs of animate land transport are perfectly illustrated by prices noted in the Roman emperor Diocletian's famous *edictum de pretiis* (price edict): in 301 CE moving grain just 120 kilometers by road cost more than shipping it from Egypt to Ostia, Rome's harbor.

Preindustrial Inanimate Prime Movers

Most preindustrial Old World societies eventually introduced simple mechanical devices to convert two indirect solar energy flows—flowing water and wind—to rotary power, and they also used sails to propel their ships. The evolution of sails shows slow progress from inefficient square sails of ancient Egypt

and classical Mediterranean cultures to triangular sails of the Muslim world, batten sails of medieval China, and finally complex rigging (flying jibs, fore, main, mizzen, topgallant, and spanker sails) of large ships that early modern Europe sent on its global conquests during the eighteenth and nineteenth centuries. Although seaborne transport was by far the cheapest alternative, it was both unpredictable and unreliable.

The best sailing ships—British and U.S. China clippers of the second half of the nineteenth century—could average more than 30 kilometers per hour for hours and came close to 20 kilometers per hour for entire intercontinental journeys, whereas the best Roman cargo vessels could not surpass 10 kilometers per hour. But all sailing ships had to resort to extensive tacking when sailing into the wind or could be becalmed by lack of winds. Consequently, grain ships sailing between Ostia and Egypt could take as little as a week or as long as three months or more, and two thousand years later homeward-bound English ships had to wait sometimes up to three months for the right wind to take them into Plymouth Sound.

The origins of waterwheels remain uncertain, but, notwithstanding such impressive examples as a cascade of Roman watermills in Barbegal in southern France, they were of limited importance in all classical societies where slave labor provided cheap energy for grain milling and manufacturing tasks. Waterwheels did become particularly important in some medieval societies where their power was used above all for food processing, wood sawing, and metallurgical processing. However, eight hundred years passed before the capacities of the largest wheels increased tenfold, and by the beginning of the eighteenth century, when they were the largest available prime movers, their European ratings averaged less than 4 kW, an equivalent of just five heavy horses. Windmills appeared only toward the end of the first millennium CE and, much as waterwheels, became eventually important in some Middle Eastern and Mediterranean countries and in parts of the coastal Atlantic Europe.

Table 2.
Sustained Power of Mobile Prime Movers

Prime Mover	Sustained Power (W)
Working child	30
Small woman	60
Strong man	100
Donkey	150
Small ox	300
Typical horse	600
Heavy horse	800
Early small tractor (1920)	10,000
Ford's Model T (1908)	15,000
Typical tractor (1950)	30,000
Honda Civic (2000)	79,000
Large tractor (2000)	225,000
Large diesel engine (1917)	400,000
Large marine diesel engine (1960)	30,000,000
Four gas turbines of Boeing 747 (1970)	60,000,000

Source: Assembled from data in Smil (1994 and 2003).

Again, however, even the relatively advanced Dutch machines averaged less than 5 kW during the eighteenth century.

As a result, societies that derived their kinetic energy almost exclusively or overwhelmingly from animate power that was supplemented locally and regionally by small waterwheels and windmills could not guarantee either an adequate food supply or a modicum of material comforts for most of their inhabitants. Nutrition remained barely sufficient even after good harvests (yields remained static for centuries), famines were recurrent, small-scale artisanal manufactures (except for a limited luxury trade) were inefficient and limited to a narrow range of crude products, typical personal possessions were meager, illiteracy was the norm, and leisure and travel were uncommon.

Fossil Fuels, Prime Movers, Electricity

All of those circumstances changed with the introduction of fossil fuels. Although people had used coal in parts of Europe and Asia in limited ways for centuries, the Western transition from biomass to coal took place (obviously with the exception of England) only during the nineteenth century (for example, in the United States wood supplied more than half of all

primary energy until the early 1880s), and in the most populous Asian countries the transition was accomplished only during the second half of the twentieth century. The oldest fossil fuels (anthracites) go back 100 million years, the youngest ones (peats) go back just 1,000 years. Both solid fuels (different kinds of coal) and hydrocarbons (crude oils and natural gases) are found in often highly concentrated deposits from which they can be extracted with extraordinarily high-power densities: coal mines with multiple seams and rich oil and gas fields can produce between 1,000 and 10,000 W/m², densities 10,000–100,000 higher than those for biomass fuels.

Moreover, fossil fuels, with the exception of marginal kinds such as low-quality lignites and peat, also have much higher energy densities: steam coal, now used largely for electricity generation, rates 22–26 MJ/kg, and crude oil and refined products rate 42–44 MJ/kg. Extraction and distribution of fossil fuels thus create energy systems that are the opposite of biomass-based societies: high-energy-density fuels are produced from a limited number of highly concentrated deposits and then distributed not just regionally or nationally but increasingly also globally. The distribution task is particularly easy with liquid hydrocarbons that are shipped by large tankers or sent through large-diameter pipelines. Not surprisingly, liquid fuels became the world's leading energy sources during the latter half of the twentieth century.

Desirable qualities of fossil fuels were greatly augmented by two fundamental technical revolutions: the invention and rapid commercial adoption of new mechanical prime movers, and by the creation of an entirely new energy system that produced and distributed electricity. Chronologically, the new inanimate prime movers were steam engines, internal combustion engines, steam turbines, and gas turbines, and their evolution has brought increased overall capacities and higher conversion efficiencies. The English inventor Thomas Newcomen's steam engines (after 1700) were extraordinarily wasteful, converting no more than 0.5 percent of energy in coal into reciprocating motion; the Scottish inventor James Watt's radical redesign

Table 3.
Sustained Power of Stationary Prime Movers

Prime Mover	Sustained Power (W)
Large Roman waterwheel (200 CE)	2,000
Typical European waterwheel (1700)	4,000
Large Dutch windmill (1720)	5,000
Newcomen’s steam engine (1730)	10,000
Watt’s largest steam engine (1800)	100,000
Large steam engine (1850)	250,000
Parsons’s steam turbine (1900)	1,000,000
Largest steam engine (1900)	3,500,000
Typical steam turbine (1950)	100,000,000
Largest steam turbine (2000)	1,500,000,000

Source: Assembled from data in Smil (1994 and 2003).

(separate condenser) raised the performance to 5 percent by 1800, and his machines averaged about 20 kW, equivalent to two dozen good horses. Before the end of the nineteenth century gradual improvements increased the power of the largest steam engines to the equivalent of four thousand horses and their efficiency to more than 10 percent.

These machines powered the main phase of nineteenth-century industrialization by mechanizing many industrial processes, expanding productive capacities, and putting the cost of an increasing range of basic consumer products within the reach of average families. Their impact was particularly critical in coal mining, the iron and steel industry, and machine construction. They also offered unprecedented power for both landborne and waterborne transportation. By 1900 railways offered scheduled services at speeds an order of magnitude faster than those of horse-drawn carriages, and large steamships cut the transatlantic crossing to less than six days, compared to the pre-1830s mean of nearly four weeks.

Their peak was short-lived however: during the last two decades of the nineteenth century small steam engines began to be replaced by internal combustion machines and the large ones by steam turbines. Internal combustion engines of the German engineer Nicolaus Otto’s motorcycle (commercialized as stationary machines after 1866 and as wheeled transport by the German engineers Gottlieb Daimler, Karl Benz, and Wilhelm Maybach starting in the 1880s) eventually reached efficiencies in excess of 20 percent. Inherently more efficient engines of the German engineer Rudolf

Diesel (introduced after 1900) reached more than 30 percent. Inventions of the 1880s, the most innovation-packed decade in history, also laid lasting foundations for the development of the electric industry with the U.S. inventor Thomas Edison’s development of an entirely new energy system (a contribution more important than his tenacious work on incandescent light), the U.S. inventor Nikola Tesla’s electric motor, and the Irish engineer Charles Parsons’s steam turbine.

Electricity provided the superlative form of energy: clean at the point of use, convenient, flexible to use (as light, heat, motion), and amenable to precise control. The latter fact revolutionized industrial production as electric motors (eventually more than 90 percent efficient) replaced unwieldy and wasteful steam-driven shafts and belts. The last of the modern prime movers, the gas turbine, was introduced for aircraft jet propulsion during the 1930s, and later it also became a common choice for generation of electricity. All of these machines were much lighter per unit of installed power than were steam engines—and hence more compact and (with the exception of large steam turbogenerators) suitable for mobile applications.

On the destructive side the Swedish manufacturer Alfred Nobel’s invention of dynamite introduced an explosive whose detonation velocity was nearly four times that of gunpowder, and even more powerful compounds followed soon. By 1945 destructiveness was raised to an entirely new level by the development of nuclear-fission weapons, with fusion bombs following just a few years later. By the time the Cold War ended in 1990 with the demise of the USSR, the two superpowers had diverted significant shares of their total energy consumption to the assembly of an incredibly destructive arsenal that amounted to nearly twenty-five thousand strategic nuclear warheads whose aggregate capacity was equivalent to nearly half a million Hiroshima bombs.

Modern Energy Systems

Every component of fossil-fueled energy systems experienced impressive gains in capacity and efficiency,

A milk seller in Brussels, Belgium, circa the 1890s. The power of wind has been harnessed for centuries to mill grain.

the combination that resulted in large increases in per capita consumption of energy. Although the world's population nearly quadrupled between 1900 and 2000 (from 1.6 billion to 6.1 billion), the average annual per capita supply of commercial energy more than quadrupled, and higher efficiencies meant that in the year 2000 the world had at its disposal about twenty-five times more useful commercial energy than it did in 1900. As a result, today's affluent economies have experienced eightfold to tenfold increases in the per capita supply of useful energy services (heat, light, motion), and the corresponding multiples have exceeded twenty-, or even thirtyfold, in such industrializing countries as China or Brazil: never before in history had an even remotely comparable gain translated into enormous improvements in the quality of life.

Gains in energy flows that are controlled directly, and casually, by individuals were equally stunning. In 1900 even a well-off U.S. farmer holding the reins of six large horses controlled sustained delivery of no

more than 5 kW of animate power; a century later his great-grandson driving a large tractor controlled more than 250 kW from the air-conditioned comfort of his cabin. In 1900 a stoker on a transcontinental train traveling at 100 kilometers per hour worked hard to sustain about 1 megawatt (MW) of steam power; in 2000 a pilot of a Boeing 747 retracing the same route 11 kilometers above the Earth's surface merely supervised computerized discharge of up to 60 MW at a cruising speed of 900 kilometers per hour.

In 2000, however, the benefits of those spectacular energy flows remained unevenly divided. When measured in metric tons of oil equivalent (toe), annual per capita energy consumption in the year 2000 ranged from about 8 in the United States and Canada to 4 in Germany and Japan, less than 3 in South Africa, 1 in Brazil, about 0.75 in China, and less than 0.25 in many countries of sub-Saharan Africa. Yet a closer look at the rewards of high energy consumption shows that all of the quality-of-life variables (life expectancy, food supply, personal income, literacy, political freedom) relate to average per capita energy use in a distinctly nonlinear manner: clear diminishing returns set in for all of these variables as the energy use increases beyond 1–2 toe/capita, and there are hardly any additional gains attached to levels above roughly 2.5 toe. This reality becomes obvious when one asks a simple question: have the lives of U.S. citizens of the last two generations been twice as good (twice as long, healthy, productive, literate, informed, or free) as those of people in western Europe or Japan?

What does a rich energy endowment do for a country? In the United States it has obviously contributed to the country's emergence as an economic, military, and technical superpower—but it could not prevent the collapse of the USSR, which was in 1989 the world's largest producer of fossil fuels. Other prominent examples of the failure to use rich energy resources to build modern, prosperous societies include such different societies as Iran, Nigeria, Sudan, and Indonesia: none of them secured vibrant economies and prosperous lives for its citizens. In contrast, three energy-poor

countries of eastern Asia (Japan, South Korea, Taiwan) became the paragons of rapid economic growth and impressive improvements in average quality of life.

Finally, energy use cannot explain the rise and fall of major civilizations and powerful societies. Such notable consolidations and expansions as the rise of Egypt's Old Kingdom, maturation of the Roman republic, unification of Han China (206 BCE–220 CE), the spread of Islam, the Mongolian conquests in Eurasia, and the enormous eastward extension of the Russian Empire cannot be linked to any new prime movers or to new, or more efficient, fuel uses. As for the declines, no drastic change of fuel base and delivery (wood, charcoal) or prime movers (slaves, oxen, horses, sailing ships, waterwheels) took place during the long decline of the western Roman Empire (the eastern part managed to survive with the identical infrastructure for another millennium), and none of the great breaks of the early modern and modern world—the French Revolution, the collapse of the czarist Russian Empire, the fall

of Nationalist China, the collapse of the USSR—could be given convincing (or indeed any) energy explanations.

Energy resources and uses are, undeniably, among the critical variables whose specific and unpredictable combinations determine the fortunes of societies. They promote, restrict, or complicate many economic and individual options, and once in place they are critical for setting the tempo of life and the levels of general welfare. Immutable dictates of thermodynamics also mean that higher socioeconomic complexity requires higher energy flows. This undeniable relationship is not a matter of continuous linear progress, however, but rather one of a relatively early saturation. Moreover, possession of abundant energy sources or their high consumption cannot guarantee well-functioning economies, decent quality of life, personal happiness, or a nation's security. Energy sources and uses constrain our actions but do not dictate our choices, do not assure economic success, and do not condemn civilizations to failure. In the modern world the only inescapable consequences of

The release of atom power has changed everything except our way of thinking . . . the solution to this problem lies in the heart of mankind. If only I had known, I should have become a watchmaker. • **Albert Einstein (1879–1955)**

Table 4.
Energy of Weapons

Projectile	Kinetic Energy of Projectile (J)
Arrow from a bow	20
Arrow from a heavy crossbow	100
Bullet from a Civil War musket	1×10^3
Bullet from an assault rifle (M16)	2×10^3
Stone ball from a medieval cannon	50×10^3
Iron ball from an eighteenth-century cannon	300×10^3
Shrapnel shell from World War I artillery gun	1×10^6
High-explosive shell from a heavy World War II antiaircraft gun	6×10^6
Depleted uranium shell from M1A1 Abrams tank	6×10^6
Hijacked Boeing 767 (11 September 2001)	4×10^9
Explosives	Energy Discharged (J)
Hand grenade	2×10^6
Suicide bomber	100×10^6
World War II gun shrapnel	600×10^6
Ammonium nitrate-fuel oil (ANO) truck bomb (500 kilograms)	2×10^9
Hiroshima bomb (1945)	52×10^{12}
U.S. ICBM warhead	1×10^{15}
Tested Novaya Zemlya fusion bomb (1961)	240×10^{15}

Engines of History

Divine, secular, and political forces have been given primacy as the chief drivers of history over the centuries. These forces evolved from the Mandate of Heaven to Marxism. Rapid upheavals of the twentieth century, along with technological change and the increasing awareness of human impact on the biosphere, have invited a recasting of history that takes into account scientific processes of which humans were previously unaware.

Human beings like to understand what goes on around them, and historians, being human, like to understand what they write about. They do so by finding causes even for the most surprising events. This was true from the start. Herodotus (484–425 BCE), for example, set out to explain how a few small Greek cities had been able to defeat an immense Persian army and navy, while the first historian of China, Sima Qian (c. 145–86 BCE), sought to explain how China's ruling dynasties rose and fell. Herodotus found a twofold explanation: free men, he said, fought willingly and more bravely than Persian subjects, forced to obey a mighty king; moreover, the king's overweening pride also offended the gods, who sent storms to damage his invading fleet. Similarly, Sima Qian invoked both human and supernatural causes. According to him a ruler's virtue allowed him to rule well and therefore attracted the Mandate of Heaven, but when rulers ceased to be virtuous, heaven withdrew its mandate, and good government broke down until a virtuous new ruler emerged to found another ruling dynasty.

These ideas about what made history happen the way it did proved to be very influential. Until about

a hundred years ago, China's historians continued to organize their histories around successive dynasties empowered by the Mandate of Heaven. And the idea that freedom made men successful in war (and also in peace) appealed to Romans as well as to Greeks, and reentered European consciousness with the Renaissance.

But in the world as a whole, the Hebrew prophets' idea that Almighty God governed history, punishing peoples and persons for their sins, and rewarding scrupulous obedience to his will, played a more influential role, dominating Jewish, Christian, and Muslim societies from the inception of those religions. For believers, Divine Providence remained inscrutable to everyone except specially chosen prophets. Yet ordinary chroniclers and historians took God's will for granted as the decisive force behind everything that happened. Other causes, when they bothered with them, were only subordinate instruments of God's will. Hinduism and Buddhism, on the other hand, treated the visible world as an illusion and paid scant attention to human history. Instead religious speculation about endless cycles of reincarnation reduced everyday events to transient triviality.

The Importance of Animism

Behind and beneath these civilized literary traditions lay a much older interpretation of the world that modern anthropologists call animism. Its basic tenet is that natural objects are inhabited by invisible spirits and share the spectrum of cooperation and conflict that humans exhibit in everyday interactions with one another. Spirits can also move about invisibly, entering and leaving a person or object at will. Hence

Horus, the falcon-headed god often associated with Egyptian pharaohs, wears the white and red double crown of Upper and Lower Egypt in a drawing inspired by a mural at the Temple of Isis.

New York Public Library.

the world of spirits exactly parallels human societies. Individual spirits work their will when they can, submit when they must, and influence everything that happens to human beings.

The earliest bands of human foragers carried these ideas with them around the Earth, and they still permeate common speech as, for example, when historians refer to the “spirit of an age.” Later religions made room for spirits, too, in various forms: angels, devils, saints, and ancestors to whom ordinary persons could

appeal for help in time of need, or, as the case might be, drive away by appropriate rituals. As such, animism is the longest lasting, most pervasive worldview that human beings have ever conceived. Throughout most of the past, the coming and going of spirits and the clash of their individual wills convincingly explained dreams, sleep, and death, as well as illness and trance and why human hopes and expectations were so often disappointed by experience. Experts in the supernatural sought to navigate among the spirits, driving some away, appeasing some, and keeping others close by for help in time of need. All religions of the world descend from and incorporate the notion that we are surrounded by a society of powerful spirits, affecting everything that happens.

Yet curious persons could never refrain from trying to fill in the gap between invisible supernatural powers, variously defined by local religion and folk practice, and whatever it was that actually occurred. As long as historical changes remained so gradual as to be imperceptible, it was possible to believe that everyday surprises and disappointments remained fundamentally the same across time. In such societies, belief in the overriding power of gods and spirits remained thoroughly persuasive. But when new forms of government, new economic activities, and new information about distant peoples and places upset old customs and expectations, new-sprung prophets, philosophers, and historians came into their own by investigating more closely the world of people and things and its relationship with supernatural powers. This was the context within which the Buddha (Siddhartha Gautama), the Hebrew prophets, and Chinese and Greek philosophers, as well as Herodotus and Sima Qian did their work.

Greek and Roman Influences

Among the Chinese, the idea of a dynastic cycle, supervised by a vaguely personified heaven, remained central and seldom challenged. Greek historical ideas were more volatile. Some, like the poet Hesiod (c. 700 BCE), held that all changes were for the worse, declining from an age of gold, to silver, bronze and

then of iron, amidst which the poet found himself. Yet the story of how Prometheus stole fire from the gods, and empowered humankind by that gift, implied the opposite idea that humans had in fact accumulated skills, knowledge, and power across time.

Nor did Herodotus's ideas seem adequate to historians after him. Thucydides (c. 460–404 BCE), for example, refrained from even mentioning the gods, and explained the course of the Peloponnesian war by emphasizing deliberate public decisions, influenced by the personal character of individual leaders. Yet he also recognized more general processes at work: how Athens' tyranny over other cities provoked eventual defeat; how the hardships of war disrupted commonality among fellow citizens, provoking civil strife, and how pursuit of honor gave way to greed. Later Greek historians, most notably Polybius (c. 200–118 BCE), elaborated the idea that a natural cycle existed whereby political power passed from monarchy to aristocracy and then degenerated into democracy. Polybius argued that the rise of Roman power—his principal subject—was due to Rome's mixed constitution, balancing monarchical, aristocratic, and democratic elements.

Almost two centuries before Polybius wrote about Rome, the conquests of Alexander the Great (Alexander of Macedon, 356–323 BCE) conquests brought Greeks into far closer touch with Egypt and western Asia than before. Accordingly, Hellenistic scholars set out to link the Greek past with that of Egypt and western Asia by constructing parallel chronologies. About 200 BCE, an Egyptian priest, Manetho, organized Egyptian history into thirty dynasties that are still used; and at almost the same time, a Babylonian priest, Berosus, summarized Mesopotamian history—before and after the Flood—down through Persian times. Both wrote in Greek, perhaps at the command of the new Macedonian rulers; and simultaneously Eratosthenes of Cyrenaica, (c. 276–194 BCE), most famous for his accurate geometrical measurement of the circumference of the Earth, arranged Greek history around quadrennial Olympiads dating back to 776 BCE.

All too obviously, history was expanding geographically and chronologically, and persuasive ideas

to explain all the surprising things that kept on happening were in short supply. In Roman times, the idea that unvarying natural law, as conceived by Stoic philosophers, ruled the universe had to compete with the notion that Fortune, conceived as a whimsical goddess, favored some and destroyed others for no reason at all. The leading Roman historians emphasized individual moral character, and both Livy (59 BCE–19 CE) and Tacitus (56–120 CE) regretted the end of republican liberty, arguing that moral decay was what had led to civil war and imperial government in their lifetimes.

Advent of Judaism, Christianity, and Islam

Judaism, Christianity, and Islam superseded discrepant pagan ideas about history by recognizing God's almighty will, operating always and everywhere. Jews, Christians, and Muslims agreed that the main lines of the world's history were revealed in sacred scripture. History began with creation, and centered not on war and politics, as pagan historians had assumed, but on how God had revealed his will to humankind, and on the always-imperfect efforts people made to obey and observe his instructions. Holy Scriptures also predicted that the world was destined to end suddenly with a Day of Judgment, when God would reward and punish the living and the dead, sending everyone eternally to heaven or to hell.

However convincing this overall pattern of history might be, short-term surprises remained as puzzling as before. But for many centuries the authority of sacred scriptures, and of codified interpretations placed upon them by religious experts, remained authoritative. Correspondingly, historical writing became intellectually impoverished since miracles abounded, and easy invocation of God's will explained everything. To be sure, pagan classical writers were never entirely forgotten, and writers like Eusebius (flourished 313–337 CE) and Orosius (flourished c. 414 CE) made rather hasty efforts to fit a few highlights from the pagan political past into the biblical narrative. New habits of citing and quoting sources make even

Not all that is presented to us as history has really happened; and what really happened did not actually happen the way it is presented to us; moreover, what really happened is only a small part of all that happened. Everything in history remains uncertain, the largest events as well as the smallest occurrence. • **Goethe (1749–1832)**

the most credulous Muslim and Christian chronicles of interest to modern scholars; and the universal framework of sacred history—from Creation to the Day of Judgment—made it easy to introduce new peoples, states, and regions into the historical domain as they became known to Christians and Muslims. More important, the universal character of God’s power invited believers to construct all-embracing chronologies, beginning with Creation for Jews, with the birth of Christ for Christians, and with Muhammad’s flight to Medina for Muslims. Despite the awkwardness of running numbers backward before the Christian and Muslim eras, these chronologies remain in use today, though most historians now substitute the religiously neutral label “Common Era” when using the Christian scheme for dating events.

After 1000 CE, trade intensified and information about distant places and peoples expanded across the Old World, and inherited religious explanations began to demand more detailed analysis. How did Heaven or God—or any other sort of ultimate power—use intermediate causes to direct human history? How indeed? Both Byzantine and Italian scholars looked afresh at ancient texts for helpful hints, but most were satisfied with rather superficial rhetorical borrowings from pagan writers. To explain the rise and fall of Cesare Borgia, for example, Niccolò Machiavelli (1469–1527) fell back on the goddess of Fortune without really believing in her existence.

In North Africa, however, the Muslim Ibn Khaldun (1342–1406) generalized from the political tumult of his times, arguing that superior social cohesion among nomad tribesmen allowed them to conquer urban dwellers only to see their initial cohesion weaken under urban conditions, thus making way for a new conqueror. His concept of ever-fluctuating “social cohesion,” and his recognition of systematic social change throughout Muslim society in the wake of the Black Death, which had killed both his parents, departed from anything historians had thought of before. Perhaps because they were so novel, his ideas survived very slenderly in Muslim lands, and came to European attention only after 1860.

Giambattista Vico (1688–1744) resembled Ibn Khaldun in the originality of his ideas about what made history happen. His principal book, *Scienza Nuovo* (1725) offered a speculative and evolutionary view of world history, according to which each successive age was characterized by dominant ideas and ideals, expressed in religion and poetry, and developed its own distinctive patterns of behavior. He remained devoutly Christian, but elaborated more systematically than anyone before him how Divine Providence allowed selfish and often brutal humans to change their thoughts and actions from age to age.

North of the Alps, the religious upheaval of the Reformation and Counter-Reformation dominated historical thinking from 1517 until about 1750. Protestants argued that the Roman Catholic Church had departed from authentic Christian practice as recorded in the Bible; Catholics attributed such practices to apostolic tradition, faithfully transmitted from Peter to the popes of Rome. This was an historical question, and generations of scholars argued back and forth, developing new information, new linguistic skills, and rules for correcting copyists’ errors in ancient and medieval texts—but never achieving anything like agreement. After 1499, the Muslim world, too, split more sharply than before between Sunni and Shi’a versions of Islam; and, as in Europe, bitter controversy fortified disagreement, without enlarging historical knowledge as much as in Europe, thanks largely to pious restrictions on resort to printing.

Eighteenth and Nineteenth Century

Beginning about 1750 more and more Europeans tired of religious controversy and the warfare it provoked. Secular, anticlerical, and sometimes consciously irreligious ideas proliferated, especially in France and England. Distinguished historical expressions of this change in the climate of opinion include Voltaire’s *Essai sur les mœurs* (1756); William Robertson’s *History of the Reign of Emperor Charles V* (1769), and Edward Gibbon’s six-volume *The History of the Decline and Fall of the Roman Empire* (1776–1788). These historians discarded prevailing notions about

the active intervention of Divine Providence in human affairs, believing that God, if he existed, had created the world as a self-regulating machine, leaving full responsibility for what happened in history to human beings. Voltaire expanded the scope of history to embrace everyday customs around the world including distant China—whose civil polity he admired because it did without priests and revealed religion. Robertson dealt with the storms of the Reformation era without clearly taking sides. And Gibbon's history traced the triumph of "barbarism and religion," that is, of Christianity and Islam, which, he argued, eventually brought the Roman Empire to an end in 1453.

European historical ideas took new forms with the rise of nationalism, accelerated by the French Revolution and the Napoleonic wars that followed. Many Germans, reacting against French political and cultural primacy, accepted the idea that a distinct national spirit inhered in their own and every other language. Johann Gottfried von Herder (1744–1803) was an influential advocate of this idea, and when medieval and modern history became a regular subject for lecturing and research in German universities after 1815, academic history took off as never before. As the study of history spread to universities in other countries, written histories quickly assumed distinct and diverse national forms. Ideas about what guided history multiplied correspondingly.

Three more or less distinct schools can perhaps be distinguished. One was conservative, idealist, and Christian, believing that each nation had its own proper place in God's plans for humankind, and therefore inherited institutions and practices that appropriately expressed the spirit and destiny of each people and state. A second was liberal, progressive, and somewhat less sure of being able to discern God's hand in history. For the English-speaking world, Lord Acton (1834–1902) more than anyone else defined this view through a history of liberty he projected but never actually wrote, and more concretely by planning a collaborative multivolume *Cambridge Modern History*, embodying the liberal view, that was published soon after his death. Both conservatives and liberals were challenged after 1848 by socialist, materialist, and godless Marxism. Yet Karl Marx (1818–1883), in

rejecting the Christian version of history, reproduced its principal features, claiming that private property had supplanted primitive communism (equivalent to leaving the Garden of Eden), but changes in the pattern of class warfare that had followed were destined to come to a speedy end when the proletariat, created by modern industry, would take power and restore justice, equality and communism by accepting the principle, "From each according to his ability, to each according to his need."

The conservative tradition emphasized national, political history and the rise of an international balance of power, adjusted from time to time by war and diplomacy. Liberals emphasized the progress of constitutional freedom across the centuries and congratulated themselves on its approach to perfection in their own time. Socialists emphasized economic history, class conflict, and the international solidarity of the working class. All agreed that human beings made their own history, but since individual and collective wills clashed perpetually, results were never exactly what anyone hoped or intended.

Twentieth Century and Beyond

World Wars I and II tended to discredit all three historical traditions. Balance-of-power politics enhancing national rivalries and provoking such destructive violence were not truly conservative, resulting in revolution instead. Freedom to fight and die in the trenches was not an acceptable climax to the advance of constitutional liberty either. And the international solidarity of the proletariat was everywhere betrayed in 1914, even though Communist revolution in Russia created a rival social and political order challenging other states after 1917; after World War II China and several other countries also became Communist as well.

Historians were rather slow to adjust their ideas to these upheavals. It was easier to persist in conservative, liberal, and socialist modes of thought and not ask large questions about overall patterns and universal causes. In Communist countries, official policy enforced ideological conformity and history soon became mere apologetics for the government of the day. Elsewhere, new themes multiplied, study

of new peoples penetrated academic history departments, especially in the United States, and increasingly minute specialization prevailed.

Resulting multiplicity makes it hard to pick out important new ideas about the course of history and the factors that affect it. Rapid globalization since 1950 pushed towards taking world history more seriously than before. New awareness of ecology and the radical impact of recent human activity on other forms of life raised new questions about the human past. The extraordinary multiplication of human numbers drew attention to demography as a fundamental variable as well. More generally, recognition that we are inescapably part of much larger evolutionary processes—cosmological, terrestrial, biological, and human—invited a recasting of history to take account of processes of which humans were previously unaware, yet which influenced or even controlled what they were able to do. Histories limited to criticizing and correcting surviving written records about what people said and did had kept historians busy in the nineteenth century. That no longer seemed in the least adequate to describe what really happened. But how to disentangle the enormous complexity of disparate processes within which we exist remains an open question. Very likely, human intelligence and our use of language will never be able to find answers that satisfy everyone.

Still within the past half century, historians have come to understand far more than before about human origins and what used to be called prehistory, thanks to archeological discoveries, anthropological studies of surviving bands of foragers, and observation of bands of chimpanzees and our other close relatives. Similarly, advances in epidemiology allowed historians to understand far more about how disease organisms and human populations have interacted across time. Energy flows sustaining human activity offer a promising way to construct quantitative estimates of our quite extraordinary success in enlarging our ecological niche at the expense of other species. Moreover, human webs of communication, permitting more extensive and efficacious cooperation across time, seem responsible for the collective

learning and the accumulation of skills that produced this amazing result.

In general, by assimilating history to sister sciences, or more exactly by making all the sciences historical, we can hope for an improved understanding of ourselves and everything around us. For it is now apparent that all the sciences evolve across time, and the physical, chemical, geological and biological processes they study are likewise time sensitive. Change pervades the universe. Human changeability is unusually rapid and, at least on a terrestrial scale, is unusually significant as well, since we are and have long been capable of upsetting all the life-forms around us, thanks to actions coordinated by language and more recently by mathematical symbols and digitalized signals as well.

A few historians have begun to attempt this bold synthesis. Among them, David Christian with *Maps of Time* (2004), is the most notable. But the task is just begun, and who knows what may follow? Human history is always surprising and sure to remain so. Authoritative religions may again simplify the task of making sense of what happens. Sudden collapse of existing high-tech urban societies cannot be ruled out. Human survival itself is problematic. Or we may learn enough to navigate the future for a long time to come just as successfully, and as precariously, as our predecessors did. Time, as always, will tell. And all the while, historians' ideas will continue to reflect changing conditions within the societies they live in.

Enlightenment, The

The Enlightenment, a philosophical movement in eighteenth-century Europe, rejected traditional social, religious, and political ideas and adopted rational thinking as a way to develop new theories accounting for human behavior and feelings. These new explanations were then applied to the social and political spheres, changing the way people viewed and thought about government, and directly influencing the development of the modern world.

The Enlightenment designates a period of European intellectual history from the late seventeenth to the late eighteenth century that brought together ideas in moral and natural philosophy and shifted inquiry away from metaphysics and the supernatural toward a focus upon physical and human nature. More significantly, the Enlightenment represented the adoption of a critical attitude toward inherited cultural and intellectual traditions. The forty-volume *L'Encyclopédie* (1751–1772), compiled by the important Enlightenment thinkers Denis Diderot (1713–1784) and Jean Le Rond d'Alembert (1717–1783), idealized the Enlightenment thinker, or *philosophe*, as one who “tramp[le] on prejudice, tradition, universal consent, authority, in a word, all that enslaves most minds,” and “dares to think for himself” (Diderot 1751, 5:270). A generation later, the German thinker Immanuel Kant (1724–1804) defined the Enlightenment as a process of freeing oneself from what he called “self-incurred tutelage,” and he wrote that the motto of the Enlightenment ought to be “*Sapere aude!* ‘Have courage to use your own reason!’” (1988, 462).

Expanding the Intellectual Sphere

The Enlightenment took advantage of new forms of intellectual exchange. Enlightenment thinkers like David Hume (1711–1776) railed against the exclusivity of earlier generations and insisted on bringing knowledge out of the pedantic world of the closeted learned to the sociable world of polite conversation in academies, debating societies, salons, and coffeehouses. Along with the expansion of the sphere of oral communication went a similar expansion of readership and print culture. In this period books became smaller, cheaper, and therefore more accessible. This time witnessed the birth of the periodical press, of newspapers and magazines. Changes in print production went along with changes in how readers related to print. Gone were the days of laborious reading; instead expanding literacy, particularly among middle-class men, meant that expanding audiences read pamphlets, essays, novels, and newspapers in their leisure time.

Physical and Human Nature

The sixteenth and seventeenth centuries saw European thinkers challenge inherited ideas about the physical universe. Medieval thinkers had built elaborate cosmological systems upon classical, and particularly Aristotelian, foundations. But in many fields, such as physics, applied mathematics, and especially astronomy, new discoveries and explanations put forward by Nicolaus Copernicus (1473–1543), Galileo Galilei (1564–1642), and Sir Isaac Newton (1642–1727), among others, challenged the picture

Education is a progressive discovery of our own ignorance. • John Dryden (1631–1700)

of a finite, Earth-centered universe and replaced it with a potentially infinite universe and a sun-centered system. Explanations of the physical universe thus increasingly presented it as analogous to a mechanism, governed by rational, mathematically expressible rules, which a divine power may have created but with which it did not need to interfere.

This shift to mechanistic explanations was also apparent in moral philosophy. Seventeenth-century thinkers like William Harvey (1578–1657), Thomas Hobbes (1588–1679), René Descartes (1596–1650), and John Locke (1632–1704) developed new medical and psychological theories to account for human movement, behavior, feeling, and thinking as governed by mechanical principles. The *philosophes* then developed economic, social, and political theories that challenged the belief in a divinely instituted and intuitively recognizable order. Enlightenment thinkers viewed human nature in terms of a morally neutral *tabula rasa*, or blank slate, that could be molded in various ways. They applied the idea of a social *tabula rasa*, or *state of nature*, to explain how civil society might have emerged and ought to be governed. Many Enlightenment thinkers, such as Hobbes, the Marquis d'Argenson (1694–1757), Montesquieu (1689–1755), and Jean-Jacques Rousseau (1712–1778), argued that political stability could be guaranteed by organizing society as a machine in which each component worked in harmony with the rest. Still others, like Locke in his *The Second Treatise of Government* (1689), used the idea of a state of nature to define the boundaries of state power in guaranteeing political stability.

Progress and Utility

During the seventeenth century, European intellectuals quarreled over whether contemporary “modern” European thinkers had surpassed their “ancient” Greek and Roman counterparts, and this debate gave rise to the Enlightenment belief that better ways of thinking and behaving had emerged in recent decades. The sense of modern improvements led to a faith among the *philosophes* that the new ideas and methods would guarantee indefinite progress in politics, society,

and the arts and sciences. The *philosophes* took up the cause of improving their social and natural surroundings through experiment and reform. Societies and academies, such as the English Royal Society, emerged in which innovative ideas and techniques were presented, debated, and recommended. From agricultural techniques to zoological taxonomies, progressive reform was an important Enlightenment ideal associated with another Enlightenment principle: utility. Hume (1902, 183) wrote that “public utility is the sole origin of justice.” In their emphasis upon principles of progress and utility, most Enlightenment thinkers were the heirs to the “moderns” in the quarrel of the ancients and moderns.

Religion and Politics

But the Enlightenment cannot be equated easily with the rise of modernity if we understand modernity to mean atheism and democracy. As often happens with any movement critical of established institutions or ideas, definitions of the Enlightenment have been constructed as much by its enemies as by the *philosophes* themselves. An appreciation of the Enlightenment must therefore go beyond commonplace definitions that tend to see it as simply challenging the authority of church and state, of Christianity and absolute monarchy. Indeed, with few exceptions, Enlightenment thinkers were defenders of both.

The Enlightenment's religious outlook was built partly upon the ideas of certain dissenting Protestant sects, such as Socinians (who denied the divinity of Christ, and consequently the Trinity) and Arians (who believed that the Son was not of the same substance as the father), and also partly upon the skeptical and humanistic traditions within Roman Catholicism. In fact, the very term *enlightenment* had already been used by Christians to designate divine inspiration. But many Enlightenment thinkers reacted to what they criticized as the “enthusiasm” of religious dogmatists and the “fanaticism” of religious wars, such as the French Wars of Religion (1559–1598), the English Civil Wars (1638–1660) or the Thirty Years War (1618–1648). They emphasized the need rationally to

Hume wanted to expand knowledge of the pedantic world into the sociable world of polite conversation in academies, debating societies, salons, and coffeehouses. New York Public Library.

reexamine the foundations of beliefs. These individuals insisted that religion ought to agree with reason and that any belief not derived from observation of the world or from human reason ought to be rejected. These thoughts encouraged the tolerance and rationalism that gave rise to the ideas of deists like Voltaire (1694–1778), who argued for a pared-down, “reasonable” Christianity emptied of its dogma and ritual, as well as those of atheists like Hume and the Baron d’Holbach (1723–1789).

The Enlightenment’s political outlook similarly mixed continuity with the past and a critical perspective on traditions. Although their enemies often accused the *philosophes* of corroding political order and the established monarchy, most *philosophes* actually favored monarchy. George III in Great Britain, Louis XV and Louis XVI in France, Frederick the Great in Prussia, Joseph II in Austria, and Catherine the Great in Russia all gave support to and were supported by Enlightenment thinkers. Influenced by the Enlightenment principle of maximizing utility, these monarchs tried to institute reforms in their kingdoms. Thus Enlightenment thinkers like Voltaire actually

advocated a form of “enlightened despotism,” or the rule of a single sovereign with absolute power to reform society. Two things that Enlightenment political *philosophes* tended to oppose were what they called “Oriental despotism,” the kind of arbitrary rule they associated with Islamic states, and the customary privileges enjoyed by certain groups, like aristocrats and guilds, which they saw as inefficient and inequitable.

The Enlightenment and the Wider World

Although the Enlightenment was almost exclusively a European phenomenon, the wider world played a key role in the development of Enlightenment thought. Descriptions of previously unknown species of animals discovered in distant lands led natural historians, such as Carolus Linnaeus (1707–1778), to develop new taxonomical systems that could effectively organize the growing mass of information regarding plants and animals. Discoveries of fossilized plants and animals also led many to abandon the practice of interpreting scriptural accounts of the world’s creation literally. Instead *philosophes* like Georges-Louis Leclerc de Buffon (1707–1788) argued that the Earth was formed and transformed at extremely slow evolutionary rates and as the result of natural occurrences such as volcanic activity and tides.

European encounters with non-Europeans and their languages, religions, and political practices also stimulated Enlightenment thinkers in many ways. Philologists such as Sir William Jones (1746–1794), who recognized the affinities between Persian and European languages, set the stage for nineteenth-century comparative grammarians. Jesuit missionaries in China, impressed with the virtue of the people they encountered, emphasized parallels between Christian and Confucian beliefs, and many Enlightenment thinkers, such as Matthew Tindal (1653–1733) and Gottfried Wilhelm Leibniz (1646–1716), pointed to China in arguing against the need for revelation, and for the idea that the tenets of natural religion were apparent to all reasonable and

observant people. The Scottish thinker Henry Home (1696–1782), noting the radical physical differences between peoples around the world, argued for the polygenetic origins of human races, an argument that contradicted scriptural accounts.

The tendency of Enlightenment thinkers increasingly to compare their own society to those of recently discovered and distant peoples challenged traditional notions in many other ways. Locke, for example, in his *Second Treatise on Government* (1690), noted that “in the beginning, all the world was America” (Locke 1993, 285). Though very few had traveled outside Europe, Enlightenment thinkers frequently used descriptions of distant cultures to comment on their own countries. One of the commonplaces of the Enlightenment was the image of the American Indian, and later of the Pacific Islander, as existing in a state of nature without literature, religion, laws, or political and social distinctions. The French aristocrat Louis Armand de Lahontan (1666–1716), for example, popularized the figure of the American Indian as living in this enviable state through the publication of fictional dialogues between a Huron and himself. In these dialogues, the Huron gets the better of his European interlocutor on such subjects as marriage, religion, and jurisprudence. Lahontan’s work was discussed by important European thinkers such as Leibniz and influenced ideas of natural law and natural religion. Lahontan’s *A Conference or Dialogue between the Author and Adario, a Noted Man among the Savages* (1703), and other works like Montesquieu’s *Persian Letters* (1721), Voltaire’s *Ingenuous* (1767), and Oliver Goldsmith’s (1730–1774) *Citizen of the World* (1762), popularized the Enlightenment genre of the imaginary traveler from a distant land who comments critically upon European customs. Indeed, this was one of the most important vehicles through which European audiences imagined non-Europeans and criticized customs within their own society.

The Enlightenment’s encounter with non-Western societies also promoted the rise of what we now call the social sciences. Sociology, ethnography, anthropology, psychology, economics, political economy,

and even literary criticism all grew out of the Enlightenment. Enlightenment historians studied how each human society followed a definite and, for most *philosophes*, progressive development from a hypothetical state of nature to civilization. This “conjectural history” implied definite hierarchies of cultures, and the Enlightenment was an important period in the development of cultural particularism, which fed into the nationalist and racist ideologies of the nineteenth century.

But since the Enlightenment thinkers saw differences between peoples as cultural, historical, or environmental rather than racial, they tended to see human nature and dignity as shared in common among all peoples. This view played a large role in the development of Enlightenment cosmopolitanism, the idea that the *philosophe* is a citizen of the world more than of any nation-state with its accidental traditions. Another important implication of this emphasis on a shared human nature was that many Enlightenment thinkers, such as Diderot and the Abbé Raynal (1713–1796), condemned slavery as an immoral and inhumane practice and played a role in the development of the abolitionist sentiment.

Enlightenment and Modern Political Revolutions

One of the perennial questions surrounding the Enlightenment is the extent of its influence, particularly on the political and social revolutions in Europe and in European colonies in the Americas. As noted above, most Enlightenment thinkers did not advocate either political revolution or republicanism. In fact, in some ways, the very concept of the Enlightenment as a coherent movement, critical of established political institutions and ideas, was created as much by revolutionaries seeking retrospectively to justify their actions intellectually as by the ideas of the *philosophes* themselves or the assertions of their enemies. There can be no question, however, that certain American revolutionaries, like Thomas Jefferson (1743–1826) and Thomas Paine (1737–1809), were influenced by Enlightenment ideas and that Rousseau in particular

had a tremendous impact on the course of the French Revolution. Simón Bolívar (1783–1830), the “liberator” of South America, learned from his tutor about Rousseau and Voltaire, and while traveling in Europe he absorbed Enlightenment ideas from such thinkers as Alexander von Humboldt (1769–1859). The idea of a written constitution, of freedom from arbitrary and unjust customs, of equality before the law, and, to some extent, of checks and balances within government were all concepts advanced by Enlightenment thinkers. In these ways, as well as others, many of which are noted above, the Enlightenment contributed much to the emergence of the modern world.

Environmental Movements

Although the term *environmentalism* was not used until much later, the roots of environmental movements date back to the 1800s, when demands for cleaner water and air and the protection of wilderness became common. Industrialization and colonialism sparked the first environmentalist voices. Though goals and intentions of the countless organizations vary, environmental movements as a whole remain an important aspect of modern society.

Environmental, or green, movements appeared around the globe during the second half of the twentieth century as people agitated in reaction to local problems, affected the policies and organization of national governments (including the origin of environmental departments in almost every nation), and helped to create national and international laws, international bodies, and important treaties. Few other popular movements spread so far, had such complex ramifications, and lasted so long with the promise of continuing influence.

To present green or environmental movements as a recent phenomenon, arising during the years after World War II, however, would be misleading. They had their roots in the conservation movement that began a century earlier. Many voices had demanded clean water and air, parks and open space, the humane treatment of animals and the protection of bird species, the preservation of wilderness, and the provision of outdoor recreation. Communities in many places began to see their welfare as being connected with the health of their land, their forests, their waters, and their clean air. Although people did not yet use the term *environmentalism*, the actions of people

to protect their valued habitats, to protest against developments that threatened to destroy them, and to search for ways to live in harmony with nature constituted an effort that has come to be known by that term.

People voiced those concerns during the late eighteenth and the nineteenth centuries when the Industrial Revolution was polluting and otherwise harming the landscape of the Western world, and colonialism was making depredations on the natural resources of the rest of the world. For example, deforestation altered small islands in the Atlantic and Indian Oceans so rapidly that European scientists who were sent out by the colonial powers noted exhaustion of timber and desiccation of climates and called for restorative action. Pierre Poivre, a French botanist, warned in 1763 that the removal of forests would cause loss of rainfall and recommended the reforestation of island colonies. Both France and Britain soon established forest reserves in their colonies, including British India. Unfortunately reserves often meant that local people were excluded from their own forests, and this exclusion produced outbreaks of resistance during the 1800s. Some European environmentalists raised their voices loudly against mistreatment of indigenous peoples. A few of these environmentalists were feminists, and some, such as the surgeon Edward Green Balfour, were willing to alarm their superiors with advocacy of not only conservation, but also anticolonialism.

The rapid sweep of resource exploitation across the North American continent aroused a few opposing voices. The artist George Catlin in 1832 advocated that a section of the Great Plains be set aside as a national park to preserve bison herds and their native

American Indian hunters. Writers William Wordsworth in England and Henry David Thoreau in the United States maintained that the authentic human self can best be realized in contact with wild nature. The Scottish-American writer John Muir became an advocate for wilderness and found many people agreeing with him. The first national park, Yellowstone, was designated in the United States in 1872, starting a movement to reserve natural areas that spread around the world. Australia declared a national park outside Sydney in 1879; Canada established Banff National Park in 1885; and South Africa in 1898 set aside an area that later became Kruger National Park. Eventually more than 110 countries established 1,200 national parks.

Through the public relations provided by many writers, including Muir, the conservation movement grew rapidly and produced many organizations. Muir's group, the Sierra Club, backed nature preservation of many kinds, successfully urging the creation of national parks and providing opportunities for its members to hike and camp in them. The Audubon Society followed in 1905, gaining protection for birds and including women leaders who convinced their peers that it was better fashion not to wear feathers in their hats. Stephen Tyng Mather, first director of the U.S. National Park Service, organized the National Parks Association in 1919 to provide support for the work of his agency. Groups appeared internationally; the World Wildlife Fund supported projects to preserve wildlife and wildlife habitats in many nations.

Voices for Sustainable Use

Not all conservationists argued for keeping natural areas in a pristine state. Some, often connected with governments, pointed out the importance of keeping reserves, especially forests, as a continuing source for needed resources such as timber. France established the Administration of Water and Forests as early as 1801, and Prussia established the Forest Service not long afterward. In 1864 the U.S. ambassador to Italy, George Perkins Marsh, published *Man and Nature*, a book warning that human-caused destruction

of forests, soils, and other resources threatened to impoverish societies everywhere. Marsh maintained that many of the changes that humans make in the natural environment, whether accompanied by good intentions or by disregard of the consequences, damage the environment's usefulness to humans. His influence was felt in the United States, Europe, and beyond, and helped to inform the movement for conservation of natural resources. In the United States that movement was exemplified by the founding of the American Forestry Association in 1875. Gifford Pinchot, who became the first chief of the U.S. Forest Service in 1905 under President Theodore Roosevelt (himself a conservationist), was a leading advocate of sustainable forest management. Pinchot had been informed by his study in French schools of forestry and by the work of Dietrich Brandis and the Forest Department in British India.

Conservationism during the early twentieth century was largely the work of committed individuals, energetic but relatively small organizations, and government land-management agencies in several countries. It was concerned with the preservation of forests, soils, water, wildlife, and outstanding natural places and the prevention of pollution in local areas, particularly in urban centers. During the years after World War II, however, more ominous and more widespread environmental problems forced themselves on the notice of people around the world to such an extent that the problems represented an environmental crisis. These problems could rarely be solved by local efforts alone: the spread of fallout from nuclear weapons testing and from accidents in nuclear power facilities, air pollution that crossed national frontiers and caused acid precipitation, persistent pesticides that lost their effectiveness even as they were applied ever more widely (and were detected in the fat of Antarctic penguins), supposedly inert chemicals that proved to attack the ozone layer, and greenhouse gases generated by countless human activities that apparently raise the temperature of the Earth. In the face of these problems, and the wider public awareness that they aroused, the conservation movement was transformed into environmental movements. The constitution of

Wildebeest graze in the Masai Mara, a wildlife refuge set aside in Kenya.

the first environmental organization under United Nations auspices, the International Union for the Protection of Nature, in 1949 defined its purpose as the preservation of the entire world biotic community. This organization became the International Union for the Conservation of Nature and Natural Resources (IUCN) in 1956.

The Emergence of Environmentalism

Environmentalism as a popular social movement emerged during the 1960s. It is often said to have begun in response to the American biologist Rachel Carson's 1962 book *Silent Spring*, which warned of the dangers of persistent pesticides such as DDT. That book dealt with only one environmental issue but found a wider international readership than any previous book on an environmental subject. Environmentalism was expressed in the first Earth Day (22 April 1970), an event primarily in the United States, although it later received international observance. By 2000 the membership of environmental organizations reached 14 million in the United States, 5

million in Britain and Germany, and 1 million in the Netherlands.

The first major international conference devoted to environmental issues was held in 1972: the United Nations Conference on the Human Environment in Stockholm, Sweden. This conference included representatives of 113 nations, 19 intergovernmental agencies, and 134 nongovernmental organizations. It marked a new awareness among nations that many environmental problems are worldwide in scope. Representatives of industrialized and developing countries attended and discussed the issues that divided those two groups. Unlike its successor conference in Rio de Janeiro in 1992, the conference in Stockholm in 1972 was not an "Earth summit." The only heads of state present were the host, Sweden's Prime Minister Olaf Palme, and Indira Gandhi of India, who served as an articulate spokesperson for views shared by developing countries. Some representatives of developing nations noted that environmentalist views were most vocal in the industrialized world—in the very nations that had reached their economic pinnacles by using natural resources from around the Earth and

A sign outside Invesco Field at Mile High in Denver (Democratic National Convention 2008), uses familiar slogans and logos to advocate recycling.

producing the major proportion of the planet's pollution. Would measures for conservation of resources and reduction of pollution limit the development of poorer countries while leaving the richer countries in relative affluence? Gandhi maintained that poverty and need are the greatest polluters and that the basic conflict is not between conservation and development but rather between environment and the reckless exploitation of humankind and nature in the name of economic expansion. She insisted that discussion of environmental problems be linked to issues posed by human needs. The Stockholm conference authorized the creation of the United Nations Environment Programme, headquartered in Nairobi, Kenya, which was given the responsibility of coordinating United Nations efforts on the environment worldwide. For example, the United Nations Environment Programme took a role in facilitating negotiation of

the 1987 Montreal Protocol for the protection of the Earth's ozone layer.

Environmental movements won legislative victories in a number of nations, creating laws to curb air and water pollution and to protect wilderness and endangered species. Most nations established governmental environmental agencies. In the United States the National Environmental Policy Act of 1969 required governmental agencies and businesses to subject development plans to environmental review.

Environmental political movements, which often emerged in the form of "Green" parties, appeared in Europe and elsewhere beginning during the 1970s. The German party, "Die Grünen" ("The Greens"), adopted a platform emphasizing environmental values, antinuclear activism, economic rights for workers, and participatory democracy, gaining support from groups other than environmentalists and winning

A bus in Athens carries a poster that exhorts, "The environment is our home."

enough representation in Parliament to wield a critical margin between left and right and to participate in coalition governments. Similar parties in other European countries generally polled under 10 percent of the vote. In the United States the Green Party received national attention during the presidential election of 2000 when its candidate, the consumer advocate Ralph Nader, may have garnered enough popular votes in some states to deprive Democratic candidate Al Gore, a moderate environmentalist and the author of the book, *Earth in the Balance*, of the electoral margin he needed for victory against George W. Bush.

Movements for environmental responsibility in business, investment, and commerce gained visibility, although the results were mixed. A movement for responsible business practices was urged by economists such as Herman Daly and Paul Hawken. Their "natural capitalism" advocated consideration of the total effect of businesses and industries in terms of social and environmental justice, and the

sustainability of the resources used, not just the financial "bottom line." Many corporations adopted green measures, although it was often hard to tell whether their efforts were genuine, or simply advertising ploys intended to appeal to buyers who wanted to make good environmental decisions.

Elements of environmental movements did not content themselves with seeking reform in governmental actions or international agreements, which seemed to them to be slow and inadequate. The Environmental Justice Movement organized protests reacting to the fact that many environmental hazards, such as toxic waste dumps and polluting industries, were located in neighborhoods inhabited by the poor and racial minorities. Protesters took direct action against environmentally damaging exploits such as the clear-cutting of ancient forests. In 1993, for example, Canadian citizens blocked roads being used by logging trucks of the MacMillan Bloedel Company to carry huge old-growth trees cut from the forests surrounding Clayoquot Sound on Vancouver Island. Police

The sign in this picture of a playground, painted in 1992 by a Russian school child living in Novozybkov (near the site of the 1986 Chernobyl accident), reads: “Closed: Radiation.”

arrested 932 protesters, who were convicted and fined from \$250 to \$3,000 for defying a court injunction banning demonstrations. An eventual agreement, however, won protection for a large portion of the forests. Nonetheless, clear-cutting continued outside the protected areas by the Weyerhaeuser Company, MacMillan Blodel's successor, and was confronted by new environmental protests.

One of the most famous environmental protests was the Chipko movement, which began near Himalayan villages in north India in March 1973 when peasants stopped loggers from cutting down trees by threatening to hug (*chipko*) the trees and place their bodies in the path of the axes—civil disobedience inspired by the nonviolent methods of Indian nationalist Mohandas Gandhi. The trees were valuable to villagers for fuel, fodder, small timber, and protection against flooding. Many demonstrators were women, who are the wood gatherers there. Similar protests occurred elsewhere in India and met with some success. In Malaysia the Penan people of Sarawak carried out a series of direct actions, including blocking roads, to protest the destruction of their rainforest homeland by commercial loggers.

Those people who have demonstrated concern for the relationship of humans to nature have often suffered for that concern. Wangari Maathai, who began the Green Belt Movement in Kenya to enable the planting and caring for trees by women and children, was beaten and imprisoned. Subsequently, she received the

1994 Nobel Prize for her environmental work. The poet and playwright Ken Saro-Wiwa was executed by the dictatorship of Nigeria in 1995 for organizing a movement against oil drilling that produced air and water pollution in the lands of his Ogoni tribe without compensation. Judi Bari, a leader of the 1990 Redwood Summer protests against the logging of giant redwood trees in California, was maimed by a bomb placed under her car seat in an attempt to kill her. Chico Mendes, who organized the *seringueiros* (rubber tappers in the Amazon rainforest of Brazil) to defend the forest and their livelihood against illegal clearing, was murdered in 1988 by the agents of rich landowners whose financial interests in forest removal he threatened. The American Catholic nun, Sister Dorothy Mae Stang, a naturalized Brazilian citizen who had worked for thirty years on behalf of the rural poor and the environment of the Amazon basin, was shot to death at the order of landowners in 2005. Appropriately, she often wore a T-shirt with the motto: “The death of the forest is the end of our life.”

One of the most striking developments in the early twenty-first century is the emergence of climate change, and specifically global warming, as the most prominent issue among those on the agenda of the environmental movement. This is the result of a growing consensus among climate scientists that the average temperature of the Earth's atmosphere and oceans has risen to a level unprecedented in recent history, to a large extent due to the release

of carbon dioxide and other greenhouse gases as a result of human activities, which shows every sign of a continued increase. The consensus has been confirmed in a series of reports by the Intergovernmental Panel on Climate Change (IPCC), a large evaluative group of scientists under the auspices of the United Nations. The possible results of this increase include losses of polar and glacial ice, rising sea level and loss of coastal land, droughts and floods in some areas, increasing energy in storms including hurricanes, impacts on agriculture, and changes in range and abundance of animals and plants. The 2007 Nobel Peace Prize was awarded jointly to the IPCC and Al Gore, former vice president of the United States, for their work in disseminating knowledge about human-caused climate change and laying foundations for actions necessary to counteract it. Among the measures urged by environmental groups are restrictions on releases of carbon dioxide from sources in industry and transportation, and support for international agreements to accomplish that purpose.

Environmental movements in recent history have proved to be extraordinarily complex, including myriads of organizations, formal and informal. Their goals have been disparate, but they share the overall goal of making the Earth a better, safer, and cleaner place for its living inhabitants, human and nonhuman. Such movements have met with many successes and many failures, and their ultimate effects are still uncertain. But they are certainly among the most far-reaching and intrinsically important movements of the modern world.

Equiano, Olaudah

(c. 1745–1797)

AFRICAN WRITER AND ABOLITIONIST

Published in 1789, *The Interesting Narrative of the Life of Olaudah Equiano . . . Written by Himself* tells the story of an African man enslaved by the British during the mid-eighteenth century. Whether it is based strictly on Equiano's life or on others, the book spares no sense of the horror and inhumane treatment slaves suffered. Equiano fought for the abolitionist cause from 1789 until his death in 1797.

Olaudah Equiano was one of the most prominent persons of African descent involved in the late-eighteenth-century effort to abolish the British slave trade. *The Interesting Narrative of the Life of Olaudah Equiano, or Gustavus Vassa the African, Written by Himself* (1789) brought to the British public a powerfully expressed African perspective on the horrors of the Atlantic crossing and the brutality of plantation life.

Equiano described his childhood in an Igbo-speaking community (in today's eastern Nigeria) and his kidnapping and transport to the west African coast, followed by a harrowing account of the Middle Passage, the forced voyage of enslaved Africans across the Atlantic to the Americas. The use of these early passages from the *Interesting Narrative* as an historical source lately has been discounted by evidence that he may have been born in South Carolina. Whether Equiano wrote the first chapters of the book from memory, or from tales heard from other Africans, or through a combination of both, the controversy should not deflect attention from the value of the narrative as a whole.

In 1754 Equiano was purchased by a British naval officer and spent most of the next eight years on royal

This portrait of Olaudah Equiano comes from the frontispiece of his autobiography, which was first published in 1789.

naval vessels; his ship participated in the Seven Years War (1756–1763) and he gives an account of the Siege

of Louisbourg, a six-week-long battle in which the British captured the fortress on Cape Breton Island from the French. He learned to speak and read English and began to acquire the skills necessary to be promoted to the rank of “able seaman” in 1762. The status of “slave” and “free” had little meaning on a ship at war; he was therefore bitterly disappointed at war’s end when his master pocketed his pay and sold him to Robert King, a West Indian merchant. King valued Equiano’s literacy, numeracy, and seamanship, but as a Quaker he was open to appeals of conscience. He agreed that Equiano might be allowed some day to purchase his own freedom, but was shocked when in 1766 the young man produced the agreed-upon sum. Equiano had saved the money through shrewd trading on his own account while tending to his master’s business.

Because his personal safety and property were still vulnerable in the Americas, Equiano settled in London. He returned often to the West Indies and the American colonies, and his years as a free sailor included voyages to the Mediterranean and to the Arctic. At one point he signed on with an enterprise to establish a plantation on the Central American coast, even supervising slave laborers as part of his duties. As late as the 1770s he was still an “ameliorationist,” believing that both moral and economic factors argued for better treatment of slaves. He expressed pride at the productivity of the slaves under his command, and the affection he asserted they felt for him.

By the next decade abolitionism was gathering force, and Equiano, now a fervent Methodist, increasingly identified with it. He hoped to journey to Africa as part of that cause, but failed in his effort to gain an appointment with either the London Missionary Society or the African Association. His best prospect was with the Sierra Leone resettlement project, but in 1787 he was dismissed from his post after his

persistent complaints about cruelty and corruption in the enterprise. Despite his African sympathies, Equiano had by then developed a strong British identity. In 1792 he married an English woman, a marriage that brought him some property and two children.

The publication of the *Interesting Narrative* provided a major stimulus to the abolitionist movement; his subscriber list included such prominent leaders as Granville Sharp and Thomas Clarkson. From the book’s publication in 1789 until his untimely death in 1797 Equiano toured Britain and Ireland promoting his book and the abolitionist cause. Though he did not live to see his dream realized, the importance of his book to the British and global abolitionist causes was well established: nine English editions appeared during his lifetime, as well as translations into Russian, German, French, and Dutch. The *Interesting Narrative* is now firmly established in the canons of both African American and Afro-British literature.

Erosion

Erosion affects crop productivity and remains the largest cause of water pollution on Earth, depositing nutrients, sediments, pesticides, and fertilizers into water supplies. There are two types of erosion: natural and human-induced. Erosion prediction and the need for soil conservation became a focus in the twentieth century under President Roosevelt's New Deal, which helped spread the word about the threats of erosion.

One of the less-appreciated constants of world history has been soil erosion, because its effects may be unnoticed before crop productivity wanes. Soil erosion causes damage in two main places: where the removal occurs and where the sediment deposits. Where the erosion occurs, it removes particles, organic matter, and important nutrients since many dissolve into water. Thus the problems of on-site soil erosion are the physical loss of the medium of plant growth, nutrient depletion, and either land abandonment or the cost of conservation and reclamation. Severe erosion has removed as much as 50 meters of soil and sediment (or more) from surfaces, creating canyons where cornfields existed a few decades before. The off-site problems of erosion are at least as severe and include water pollution, sedimentation, and property burial. Indeed, soil erosion creates the largest water pollution problem on Earth by carrying nutrients and fertilizers, sediments, and pesticides into stream channels. Sedimentation fills up channels that must be dredged, or the channel capacity decreases, which cuts down on its holding capacity and increases flooding. Sedimentation has also buried whole towns and covered many valleys with several meters of often much less fertile sediment.

History

We can view the history of soil erosion as spanning several periods. It started long before human history as geological or "natural" erosion, which is generally a slow process, but given enough time it carved mile-deep and spectacular canyons. This soil erosion occurred in several temporal modes, but it was generally slow and steady over millions of years, though it could be episodically rapid and discontinuous. A second wave started with human-induced or human-accelerated erosion, when humans became technologically advanced enough to disrupt the surface vegetation through fire and the girdling of trees. Evidence suggests that cooking fires go back over 1 million years, but evidence indicates that the use of fire to control vegetation, and thus causing erosion, clearly started as a hunter-gatherer phenomenon in the Pleistocene era (about 60,000 BCE) in what is now Tanzania.

Significant soil erosion started when humans domesticated animals and plants, removed vegetation from larger areas, and thus intensified land use. This erosion presumably began with domestication and concentrated settlement around ten thousand years ago in the Near East and later elsewhere. A third period of erosion probably started with more active trail formation, continued active removal of vegetation for settlements, and soil manipulation for seedbeds. The first actual evidence for erosion seems to lag behind the earliest evidence for agriculture. This lag is about one thousand years in Greece, where the first erosion occurred in some regions about 5000 BCE. The lag also occurred in Mesoamerica, where evidence for agricultural-induced land-use change

occurred around 3600 BCE, but the first wave of sedimentation from erosion occurred by 1400 BCE. Generally, this early erosion accelerated with the Bronze Age civilizations of Eurasia and the Early Pre-classic (before the first millennium CE) Americas as pioneer farmers ascended from the river valleys and lowlands and deforested steeper slopes in Mesopotamia, Mesoamerica, the Mediterranean, China, and the Indus Valley. Soil erosion waxed and waned in ancient cultures after this period, depending on soil conservation, climate change, and land-use intensity. In some parts of the Classic Americas (about the first millennium CE) in Mesoamerica and the Andes, soil conservation features sustained heavy soil use with high populations, though some studies argue that high soil demands and insufficient conservation figured in declines and collapses. The evidence for the Mediterranean is variable; there is some evidence for soil stability and some for erosion and sedimentation during the highly populated and intensely managed Hellenistic and Roman periods.

A fourth period of world soil erosion occurred with the vast breaking up of new lands around the world that resulted from colonial settlement during the sixteenth to the twentieth centuries. For the first time in history, large areas of previously uncultivated land fell under the plow in the Americas, Oceania, Siberia, Asia, and Africa. Moreover, farmers used to the relatively mild climates and low slopes of western Europe began to farm areas on steeper slopes with much more intensive precipitation or drier and more wind-erosion-prone conditions. These farmers were pioneers who came with little knowledge about their environments and ignored what conservation indigenous people had practiced. This ignorance led to devastating rates of soil erosion and lost land productivity.

The final period of world soil erosion came after World War II, with the expansion of mechanization and population growth fueled by better food and medicine. What once had been remote or marginal lands, such as steppes and tropical forests, became farmable due to the imperatives of high populations and the growing markets for tropical crops like coffee and bananas. Expanding populations and a variety

of displacement processes drove farmers into lands extremely susceptible to erosion, such as that in the mountains of Central and South America, Africa, and south and east Asia. The mechanics of soil erosion alone explain why recent agricultural and wood-cutting expansion upslope into hills of Haiti, Rwanda, Madagascar, and Nepal have made human-induced soil erosion the largest agent of geomorphic change on the Earth today.

Unfortunately, even recently in the United States, with its large conservation efforts and scientific capability, almost one-third of its agricultural lands are eroding significantly faster than soil is forming. Despite this, American land continues to maintain its productivity, but at the cost of several immediate and long-term problems: sedimentation (the largest water pollutant) and its ecological impact; cost of fertilizer; and more fuel use.

Soil Erosion Processes

We cannot understand the history of soil erosion without recognizing the processes of soil erosion. Soil erosion is the movement of soil particles by wind and water moving in flows, streams, and waves. Geomorphology is the science that studies the processes and forms of the Earth's surface. Other geomorphic agents also sculpt the Earth's surface over time, including glaciers, chemical dissolution, mass movements or landslides, and of course tectonic and volcanic activities. For the most part, humans speed up Earth surface dissection in some places and sedimentation in others, playing their part in such processes as landslides, sinkhole formation, and soil, stream, and beach erosion. Soil erosion can start with raindrops that fall up to about 32 kilometers per hour and impact a soil surface, dislodging and splashing particles of mineral and organic matter upward. These particles will land slightly downwind, but this will only lead to slow creep if the vegetation cover is substantial or water does not run over the surface.

This runoff or overland flow is the second important step in erosion, and it only happens when rainfall or water delivery to a point occurs faster than soil

Rocinha favela, like many favelas in Rio and other Brazilian cities, is located on a steep hillside. A gutter running along the base of the mountain diverts runoff away from the neighborhood during the rainy season.

pores can take in water (infiltration). Runoff may also occur with snowmelt or ice melt and cause accelerated erosion on surfaces from which humans have cleared vegetation or which has been plowed. Initially with runoff, water flows over the surface and removes thin layers of soil, by raindrops dislodging particles and by the force applied by water flow. This occurs first as sheet erosion as planar flows remove particles evenly from the surface, except for the more resistant soil pedestals that are often left behind as testament to former soil surfaces. This interrill erosion occurs in the belt of no channels on the upper slopes, and can be insidious because it leaves only subtle clues but may cause high soil particle and nutrient losses.

Rills (small streams) start to form downhill from interrills where flow converges and start to dissect soil channels in three directions: headcut, downcut, and laterally cut. Rills can remove large quantities of soil, including whole sections of topsoil, but farmers

can plow these out, though the plowing itself may loosen and make soils prone to erosion again. With more flow and greater turbulence, channels enlarge and tend to form in the same slopes where flows concentrate. Since plowing can expunge these larger rills, but they return in the same slope position, they are called ephemeral rills. These areas can be tilled out or left vegetated.

Gullies on the other hand are mature channels that have back, down, and laterally eroded over so large a space that normal tractors cannot plow them out. They can also be formed by waterfall erosion (runoff falls from one surface to another and undercuts the headwall surface), or by piping (water flowing underground intersects the surface, forming a surface outlet channel that erodes a larger area and undercuts surface soils that collapse along the subsurface channel). Gullies often start out being narrow and widen by channel flows undercutting their sides. Water flowing

in these channels carries water in suspension and as bed load, rolling, creeping, and saltating (bouncing) downstream.

Human landscape alteration also increases the size and frequency of mass movements on slopes, stream bank erosion, coastal erosion, and wind erosion. Wind soil erosion occurs at natural and accelerated rates as well and over a large part of the Earth, especially on flat, drier, sandier, and less-vegetated areas. The key factors in wind erosion are surface cover, soil coherence, and wind intensity and duration. In many areas where all of these conditions prevail, such as in Loess Plateau of China, which has had among the highest rates of erosion for millennia, water erosion is also very high. The processes of wind erosion starts with sediment load in a channel being carried in suspension by winds fast enough to hold up particles or those particles being rolled or saltated along the ground. Over 90 percent of the sediment is carried less than 1 meter above the surface, and all soil textures (clay, silt, and sand and even gravel) can be carried by wind, depending on aggregation, shape, and density. Winds tend to carry the larger particles like sands over shorter distances as creep or saltation. They can and do carry clays over thousands of kilometers, but clays also cohere into large enough clods that they resist deflation. Thus under normal winds, silt and fine sand is often the texture size that deflates, suspends, travels, and drops out into deposits at predictable distances from the point of erosion. These deposition areas build up and become the world's extensive loess (wind-deposited, loamy soil) deposits, like those in China, central Europe, the Mississippi Valley, and the Palouse region of Washington State, often fertile but highly erosive landscapes.

Measuring and Predicting Erosion

Humans have recognized the on-site and off-site problems due to soil erosion for millennia. Terracing started at least five thousand years ago, and structures to divert runoff were common in many ancient societies. Yet it was not until the early twentieth century that policy makers and scientists recognized the need to predict

soil erosion. In 1908, President Theodore Roosevelt recognized that soil erosion was among the most dangerous environmental challenges. But the affective response to soil erosion in the United States only came during the mid-1930s in the form of the Soil Conservation Service (SCS)—formerly the Soil Erosion Service of 1933 and now the Natural Resources Conservation Service. The SCS was the largest factor in the spread of soil conservation in the United States, made possible by President Franklin D. Roosevelt's New Deal and enthusiastically championed by H. H. Bennett, the first and most prominent director of the service. The New Deal spread the word about erosion and conservation through funding rural development, art, and science. For example, it organized conservation demonstrations and the Civilian Conservation Corps projects that built check dams and terracing around the United States. The New Deal also used science and scientific management, building predictive models by collecting more than eleven thousand so-called plot years of erosion data from around the United States under different land uses and constant slope lengths and distances. (Scientists can measure erosion using many techniques that have helped them understand both natural and accelerated rates of soil erosion. Measurement has focused on pin studies on natural slopes that have recorded truncation of soils under a variety of land uses and rain intensities and under physically and mathematically simulated conditions.)

Scientists led by Walter Wischmeier at Purdue University forged the plot data into the Universal Soil Loss Equation (USLE), a predictive equation that could be used by farmers and scientists to estimate and compare soil erosion under different crop types and conservation practices. The equation applies well to the regions in the United States from which it was empirically derived, and many studies have adapted it to many other parts of the world with variable success. The equation predicts sheet and rill erosion based on six variables: rainfall intensity, soil erodibility, slope length, slope gradient, crop types, and conservation practices (RKLSCP). Scientists further adapted the USLE into the Revised USLE (RUSLE), which is based on the same set of factors. These

Gold miners gather on site in South Africa, circa early twentieth century. Mining has been a major cause of erosion for hundreds of years.

equations have become codified as tools for policy and as important foundations of conservation planning for many land uses and are now available for use around the world from the U.S. Department of Agriculture's Agricultural Research Service (2006). Many scientists have also worked on a variety of physically based or process-oriented models that attempt to simulate the natural, physical processes of soil erosion, such as detachment. This next generation of models, such as the Water Erosion Prediction Process (WEPP) model, should more accurately predict more types of erosion and deposition across a landscape from sheet, rill, and channel erosion.

Soil Erosion in Perspective

Soil erosion has ramped up and waxed and waned through five major periods in world history. Despite twentieth-century advances in understanding soil erosion and conservation in the United States and other developed nations, the rates of soil erosion have not really waned in much of the developing world in the last

half-century. Indeed, humans today, through soil erosion, are the leading geomorphic agents on the Earth. The periods when soil erosion ramped up came as the result of technological breakthroughs and population expansions that allowed humans to alter the landscape: applying fire, domesticating animals, centralizing habitation and intensifying farming, expanding onto steeper slopes, and creating a greater demand for tropical crops. In many cases of severe soil erosion, pioneer farmers broke new lands with little understanding of them. History also shows that soil conservation arose at different times, curtailing soil losses and developing stable soil use during periods of increased population growth. The problem has always been how to sustain and preserve soil while speeding up the conservation learning curve of pioneer settlers.

Esperanto

The Polish linguist L. L. Zamenhof created Esperanto in the late nineteenth century in the hope that an international language would harmonize the peoples of the world. Widespread acceptance has continued, and in the mid-twentieth century, UNESCO affirmed the value of establishing Esperanto as a universal second language. Esperantists believe that doing so will produce positive outcomes in learning and teaching language, multilingualism, and human liberation.

Esperanto is the most successful of the roughly fifty planned language projects initiated since 1879. There are Esperanto speakers on virtually every continent of the globe. Estimates of the total number of speakers worldwide vary, though it is reasonable to assume—based on several variables including the large number of national Esperanto associations, high sales of instructional textbooks in the language, and membership data from local Esperanto societies—that those with some degree of proficiency in the language may range from several hundred thousand to several million. Esperanto is a living language that is both spoken and written. Its total lexicon contains between fifteen and twenty thousand root words that are potentially generative of myriad others.

Description

Known for its simplicity, beauty, and malleability as a medium for translation, Esperanto is considered by many to be one of the easiest languages to master. Its fundamental grammar is based on sixteen rules. In simplified form, these are as follows: (1) there exists

no indefinite article and the definite article (i.e., “the” in English) for masculine and feminine nouns is *la*; (2) all singular nouns end in *-o* (nominative) or *-on* (accusative); (3) the adjectival ending is *-a*; (4) the Esperanto lexicon contains words for the following numbers—“one” through “ten,” “one hundred,” and “one thousand”; (5) there are ten personal pronouns; (6) person and number are not indicated in verb forms, only tense and mood; the endings for the past, present, future, conditional, imperative, and infinitive are *-as*, *-is*, *-os*, *-us*, *-u*, and *-i*, respectively; (7) the adverbial ending is *-e*; (8) prepositions govern the nominative case; (9) words are read and pronounced exactly as they are written; (10) word accent falls always on the penultimate (next-to-last) syllable; (11) lexical juxtaposition is the means employed to form compound words; (12) two negative particles/words are unnecessary in any clause; (13) the accusative case is used to indicate directionality; (14) all prepositions have a definitive and unchanging meaning—in instances where the correct choice of preposition is uncertain, the word *je* (which has no exact meaning) is used; (15) foreign words are brought into Esperanto unchanged, except insofar as adjustments are needed to conform them to its orthographic conventions; and (16) an apostrophe can take the place of the final vowel that appears on either the definite article or a noun.

Esperanto’s creator, Ludwik Lejzer Zamenhof, was born on 15 December 1859 in Białystok, Poland. He was raised in a Jewish household, and his parents reinforced in him idealistic virtues that accentuated the kinship of all peoples. At home and in school, he was exposed to several languages including Russian, Polish, German, French, Latin, Greek, Hebrew,

and Lithuanian. The interethnic strife that dominated his city left a lasting impression on him, and at the age of nineteen he began working on the rudiments of what would become Esperanto. His hope was to provide an international language and unifying ideology that would bring all of the peoples of the Earth together in harmony. He published his initial tractate entitled *Lingvo Internacia* (International Language) in 1887 (in Russian). He did so using the pseudonymous attribution “Dr. Esperanto,” the meaning of which is roughly “a doctor who is hopeful.” Eventually, this fictive appellation was adopted as the name of Zamenhof’s new language. This was to be a fortuitous development because it describes well the character of many who consider themselves true “Esperantists.”

The corpus of Esperanto literature has grown over the years into one as rich and diverse as that of many national and ethnic languages. It includes novels, plays, periodicals, poetry, and exemplars from virtually all of the major literary genres. In addition, many major literary masterpieces—such as the works of William Shakespeare and even the Christian Bible—have been translated into Esperanto. National and international Esperanto associations serve as resources for those who use the language for social exchange, scientific writing, and a host of other purposes. These include the Esperanto League of North America (www.esperanto-usa.org) and the World Esperanto Association (also known as the UEA—Universala Esperanto-Asocio; for more information see www.uea.org). Both are membership organizations that provide opportunities to become part of the global community of Esperantists through conferences, receipt of newsletters and other periodicals, written correspondence with speakers around the world, and online opportunities for language learning.

In 1954 the United Nations Educational, Scientific, and Cultural Organization (UNESCO) passed a resolution affirming the value of Esperanto in establishing rapprochement between the peoples of the world, noting its positive benefit in furthering intellectual engagement, and pledging cooperation between UNESCO and the UEA. The spirit of this

initial resolution was reaffirmed in 1985 by a second resolution that celebrated the centenary of Esperanto in 1987 and empowered UNESCO’s director-general to follow closely the development of Esperanto as a mechanism for facilitating cross-cultural understanding. In 1996 the World Esperanto Congress, held in Prague, issued a manifesto calling world governments, institutions, and others to realize that use of a limited number of national languages would never result in a “fair and effective language order” that promotes democracy, global education, effective language teaching and learning, multilingualism, language rights, language diversity, and human liberation. Concomitantly, it identified the movement to promote Esperanto as a universal second language as a means to achieve the aforementioned ends.

Outlook

The growth and popularity of this planned language are evidence of its utility and the continuing vitality of Zamenhof’s vision of Esperanto as a linguistic bridge capable of connecting the world’s disparate peoples. The future of the Esperanto movement certainly merits close scrutiny, particularly as the need for effective means of communication, coalition building, and peacemaking increase in the wake of changing geopolitical realities in our postcolonial era.

Both controversial and hard to define, *ethnicity* is a term of vital importance for world history. In its most restricted form it refers to a group's shared biological origins; in its broader definition it more closely resembles the concept of nationality. In practice, ethnicity is often linked to a specific language or religion. Ethnic prejudices have led to aggression, to feelings of ethnic superiority, and ultimately to genocide.

From the earliest civilizations to the present day, cultures have differentiated themselves from others on the basis of ethnicity. In many civilizations kings and nobles belonged to a different ethnicity than townspeople and peasants. And in the nineteenth and twentieth centuries researchers attempted to define ethnicity on a biological basis, creating pseudoscientific fields such as eugenics and "race science." Even in today's transnational and globalized world, ethnicity continues to play an important role in national identity and cooperation between different nations.

Definition

Ethnicity is exceedingly difficult to define in any precise way. In different contexts, it can come close in meaning to terms such as race, national origin, tribe, or nation. At the root of the word is the Greek term *ethnos*, meaning "nation," but in the specific sense of a group of people descended from a common ancestor, a kind of large extended family. When Sumerians referred to themselves as the "black-headed people," they were identifying themselves by ethnicity. To be sure, even by 2500 BCE considerable mixing of peoples had already occurred, but the crucial fact is that the Sumerians

distinguished themselves from other cultures not only by their language and religion, but by their physical appearance and descent: that is, by ethnicity.

Ethnicity thus refers in its most restricted form to a group's shared biological origins. But in any complex society intermarriage between diverse groups occurs. Thus ethnicity is often more correctly thought of as the way people perceive their own origins rather than a biological fact. While ethnicity in its narrow sense comes close to clan or race in meaning, in its broader definition ethnicity more closely resembles the concept of nationality. So when nineteenth-century nationalists praised the long historical existence and glorious past of, say, the German or Lithuanian nations, they did so in ethnic terms. Nation, a more political term, in this way became defined and propagandized as a function of ethnicity.

Strictly speaking, religion and culture have nothing to do with ethnicity. After all, a person can convert or learn a new language, even as an adult. In practice, however, ethnicity often becomes closely linked with a specific language or religion. Thus Poles and Croats came to see their ethnic identity closely linked with the Catholic religion. Similarly, tradition and history forged a tight link between the perception of Russian ethnicity and the Russian Orthodox Church. Again it is necessary to keep in mind that ethnic mythologies are frequently more important than actual bloodlines.

Ethnicity in the Premodern World

In the premodern world, before industrialization and the political-social changes of the past roughly 250

years, ethnicity very frequently overlapped with social class. Quite unlike in modern political systems, pre-modern princes often ruled over regions of extremely mixed ethnic populations with little concern about the origins or languages spoken by their subjects. Indeed, many rulers glorified their own ethnic origins as distinct from those of the people they ruled. The Mughal rulers of what is now India and Pakistan, starting with Zahir-ud-Din Muhammad (Babur; 1483–1530 CE), remembered Central Asia as their true homeland, even centuries afterwards. Similarly, the Manchu rulers of Qing China (1644–1911/12 CE) consciously emphasized their ethnic and cultural differences from the Han Chinese they ruled. The fact that the ruling classes were of a different ethnicity than the rest of the population was perceived as quite normal.

In the premodern world, ethnic and cultural diversity was seldom regarded as a political or social problem. On the whole, ethnic groups lived separately (even in the same territory), following their own rules and religious laws, but were tolerated by the rulers as long as they paid taxes and avoided rebellion. This is the situation in much of the Hebrew Bible, which recounts the story of one ethnicity (defined originally by religion) that lived under a variety of foreign rulers, from Persians to Egyptians. We should recall that in the premodern world social and physical mobility was quite restricted. Because different ethnic groups mixed less, they also were less likely to take on each other's cultural and linguistic characteristics. That is, there was relatively little assimilation in the premodern world. Each group followed its own affairs, often guaranteed in its autonomy by the king or sultan, as in the Ottoman Empire's *millet* system, which allowed Jews, Orthodox Christians, and other ethnic groups (though defined by religion) very broad autonomy in their internal affairs.

This is not to say that assimilation did not exist in the premodern world. Any powerful and successful culture attracts imitation among people with enough time, affluence, and ambition to attempt to take on a new culture. For example, in the Roman Empire

non-Romans were actively encouraged to learn Latin, dress like the Romans, and accept Roman culture in all its forms. Thus so-called barbarians (to use the Roman term) like Franks, Visigoths, and Lombards gradually shed their original languages even while retaining important ethnic and cultural differences. With the collapse of the Roman Empire in the fifth century CE, the mixture of indigenous, Roman, and “barbarian” cultures allowed new ethnic groups like Frenchmen, Italians, and Spaniards to develop.

Even in the premodern world some cultural and ethnic mixing took place. But there were limits to these processes. For example, stark physical differences in skin color and outward appearance between Europeans, Asians, Africans, and (Native) Americans made it difficult if not impossible for, say, a Mexican or Peruvian to claim to belong to the Spanish ethnicity. In this way race precluded or at the least stymied a broader process of ethnic-racial assimilation. Ethnicity played a crucial role in “ordering” the social order of the post-Columbian New World. At the highest ranks of society were the European-born, closely followed by Creoles (of European ethnicity but born in the New World). Descending down the social hierarchy, people of mixed American and European parentage (“mestizos”) came next, with indigenous people and African slaves occupying the lowest social ranks.

Ethnicity and Nationalism

As we have seen, in the premodern world princes and their subjects frequently belonged to different ethnicities. Because premodern rulers did not derive their legitimacy from “the nation” (that is, the people they ruled over), this ethnic difference had no effect on their power. All this was to change in the nineteenth century CE with the growth of nationalism. Nationalism can be simply defined as the political doctrine that demands that all “nations” (groups of people bound together by language, culture, religion, shared history, or some combination of these factors) should have their own “states” (sovereign political units). As

Photo by Staff Sergeant Andy Dunaway.

a political movement, nationalism traces its origins back to the French Revolution, which demanded that the nation—not the king—should decide France’s politics and future. One great sticking point of early nationalism, however, was the definition of a nation. This is where ethnicity often came in. To be sure, few nationalists sincerely believed that, say, all Germans were really descended from the same ancestors, but in their rhetoric they acted as if this was the case. Some extreme cases, like the historian and racist philosopher Joseph-Arthur de Gobineau (1816–1882), specifically defined nations on the basis of ethnicity and even race. The evil consequences of such racist theories became entirely apparent with the rise of Adolf Hitler (1889–1945) to power in Germany. As part of his perverse program to “purify” the German nation, Hitler helped perpetrate one of the most appalling mass murders in history, causing millions of deaths.

In the United States, too, ethnicity played a major part in politics. Before 1864 the vast majority of African Americans were enslaved and long afterward did not enjoy *de facto* equal rights with other Americans. Asians immigrated to the United States in large numbers in the mid-1800s and helped build the transcontinental railroad (completed 1869), but they also suffered prejudice and legal disabilities. By the end of the century legal immigration from Asia (especially China) was almost impossible, while the

descendants of earlier Asian immigrants were often denied citizens’ rights.

In the last quarter of the nineteenth century and into the twentieth, European nations (joined to some extent by the United States) extended their domination over much of the rest of the world, especially in Africa. During this boom of “new imperialism,” ethnicity—usually in a racist sense—was employed as a tool to justify European control over Asians and Africans. Rudyard Kipling’s poem “The White Man’s Burden,” which urged the United States to take on the responsibilities of this imperialism, nicely sums up these beliefs.

The Age of Globalism

After World War II, racism, extreme forms of nationalism, and imperialism were explicitly rejected by the United Nations (formed 1945). Though many forms of these vicious ideologies and practices continued, few world leaders were prepared to defend theories of ethnic or racial superiority. Optimists looked forward to a world free of nationalism and racism in the near future. Unfortunately their expectations were not realized.

In the two decades after the end of World War II, dozens of new independent states were created out of former colonies, for the most part in Africa and Asia. Almost all of these new countries contained

Plate 17 from *Germania Antiqua* (1619) by Philip Clüver. The name “Barbarian,” which began as an onomatopoetic term that mimicked what foreign languages sounded like to the ancient Greeks and Romans (literally, “bar-bar”), still elicits stereotypes among ethnic groups.

a variety of ethnic groups among its citizens, often speaking very different languages and following different cultures. For example, the new state known as Pakistan was created from mainly Muslim regions of British India without consideration of its citizens’ ethnic diversity. The very name “Pakistan” was created to reflect this ethnic variety, its first letters referring to different regions dominated by diverse ethnic groups—Punjab, Afghania, Kashmir.

While British India split along religious lines (Hindu-Muslim) when achieving independence from Britain in 1947, most colonies were transformed into sovereign states without any border changes. Since colonial lines were drawn in the nineteenth century

without considering ethnic difference, African countries are some of the most ethnically diverse in the world. In many cases this has caused serious problems, including difficulties in communication among populations speaking extremely different languages. An even greater tragedy occurred in the late 1960s when the oil-rich region of Biafra attempted to secede from Nigeria. Biafra’s declaration of independence was based in part on the ethnic demands of the Ibo (or Igbo) nation against Yoruba dominance. In the end Nigerian troops crushed Biafran independence, and an uneasy truce was declared between the three main ethnic groups (Ibo, Yoruba, Hausa) that together make up some two-thirds of the country’s population.

While progress on interethnic relations has been made in Nigeria, the central African country of Rwanda witnessed a horrendous ethnic-based genocide in 1994. Two main ethnic groups, Tutsis and Hutus, dominated the small country created by Belgian colonists. The assassination of the Hutu president of the country set off a massacre of the Tutsi minority in which the majority of the country’s Tutsis were brutally murdered. In part, the Hutu hatred for Tutsis stemmed from historical factors. Tutsis had dominated the region’s politics before independence, and the Belgian colonial authorities had generally favored the Tutsi minority over their Hutu neighbors, causing widespread resentment.

Socialist states aimed to overcome ethnic hatred and create new national identities not based on ethnicity. The two best examples of such attempts are the Union of Soviet Socialist Republics (USSR) and Yugoslavia. In the USSR, officially all languages and ethnicities enjoyed equal rights. The country was divided up into fifteen “union republics” (Soviet Socialist Republics)—Armenia, Azerbaijan, Belarus, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Moldavia, Russia, Tajikistan, Turkmenistan, Ukraine, Uzbekistan—in which generally two official languages were used: Russian and the local language. Thus in Vilnius, the capital of Soviet Lithuania, street signs were always bilingual, in Russian

and Lithuanian. But with the economic problems and political fumbling of the late 1980s in the USSR, ethnic strife grew. Bloody clashes occurred in the Caucasus region, between Muslim Azeris and Christian Armenians. In the Baltic republics (Estonia, Latvia, Lithuania) ethnic pride was one tool used by local activists against the USSR, culminating in independence in the early 1990s. Considering the huge size and ethnic diversity of the USSR, it is remarkable that its collapse engendered so little ethnic violence.

In Yugoslavia the situation was different. The south Slav state had been created out of an expanded Serbia after World War I. After World War II, Marshal Josip Broz Tito (1892–1980) led the country to liberation from the Nazis, then created a socialist state in which no one ethnic group was dominant. As long as Tito lived, the compromise between Yugoslavia's diverse ethnicities lasted. In the 1980s, however, a combination of political and economic breakdowns led to ethnic massacres in the early 1990s. Once again historical memories played some role here: many Serbs remembered the murderous activities of the fascist Croatian Ustasha, which had collaborated with the Nazis during World War II and massacred thousands of Serbs and Jews. Since the Dayton Peace Accords of 1995, an uneasy peace has existed in the region, though clashes between ethnic Serbs and Albanians in the Kosovo region have flared up periodically.

In the early twenty-first century, one catchword constantly repeated is "globalization." But even while the Internet, popular culture, and international trade bring the world closer, ethnicity remains a key and defining issue in domestic and international politics throughout the world. Only the future will reveal whether humanity will learn to appreciate and celebrate ethnic diversity in a spirit of toleration and mutual respect or will take

instead the negative path of prejudice, aggression, and genocide.

Ethnobotany

Ethnobotany examines the cultural and biological relationships between plants and people, usually human populations organized into communities or linguistic groups. Ethnobotanists study how people use plants, modify habitats to benefit plant species, alter entire landscapes, and create new plants through genetic selection (domestication) and unnatural places to grow them (gardens and fields).

People without metal or advanced technology have been regarded as incapable of transforming the environment from its “pristine,” pre-European contact condition. Ethnobotanists have demonstrated through extensive fieldwork that indigenous people worldwide had the means and knowledge to modify the landscape and to create anthropogenic plant communities. In North America their interactions were extensive enough to make a “domesticated” plant environment where the actual presence of plants, their distribution, associations, quantity, and physical condition were determined by indigenous people’s behavior, utilitarian needs, and worldview.

Plant Species Management

Many techniques are used to target individual plant species to increase their productivity, ease of harvest, or spatial proximity to benefit people. Nonsedentary foragers, small-scale farmers, and agriculturists employ them. Burning clumps of a species will encourage sprouting for basketry or wooden tools. Redbud, hazel, and oak are manipulated by this means in Native California. Some plants are burned

seasonally to encourage edible seed production or greens for humans and grazing animals.

Weeding seasonally “useless” plants to reduce competition and raise visibility, shaking propagules to increase seedlings, and creating monotypic plots encourages other plants. These are forms of selective harvesting and tending. Another form of plant lifecycle intervention is harvesting plants’ subterranean roots, tubers, or bulbs with a digging stick. This technique incidentally replants root cuttings (e.g., Jerusalem artichokes and sweet flag) and bulblets (e.g., onions and camas). Through cultivation, the soil seeds are sowed, the soil is aerated, allelopaths are oxidized, and nutrients are recycled. Sedge and bulrush rhizomes for baskets grow longer from these tilling practices. Another method to assure the availability of important plants, especially rare medicines found some distance from a community, is transplanting them in a garden or protected track. A final procedure commonly used is pruning or coppicing perennial trees or shrubs for basket canes, cordage, and firewood. Breaking fruit-laden branches of serviceberry and huckleberry reinvigorated them to stimulate vegetative growth, flowering, and fruits. The Pueblo Indians in the Southwest pruned dead limbs from piñon pines for firewood and knocked the branches to stimulate growth of more nuts from a healthier tree.

Anthropogenic Ecosystems

Humans create heterogeneous environments through their broadscale management practices. Plant manipulation and harvest methods follow a multiyear cycle of plant management according to species and their

From earliest history to the present day, humans have encouraged the growth of beneficial plants and discouraged the growth weeds.

locality. The result is an ecosystem composed of a mosaic of communities maintained by human cultural practices. Wildernesses only came to be when the indigenous managers lost their land, were killed in wars or by disease, or were replaced by foreign colonists.

Fire is a common tool throughout the world to alter plant communities. Fires set locally around acorn, hickory, and other nut trees clear brush, aid collecting or, indirectly, establish shade-intolerant seedlings. By burning grasslands and berry patches, new growth is stimulated and plant competitors are eliminated. By using fire, nutrients are recycled simultaneously, pests killed, and lower stages of plant succession maintained. The overall result is a patchwork of communities characterized by species diversity and vigorous growth.

The entire landscape is not managed the same annually. Patches are burned in different years and harvests varied according to biological factors but aided by human practices of settlement, social dispersion, and even ritual regulation for determining which plants can be harvested at different times and places.

Special anthropogenic spaces are gardens. These are not a duplication of other plant communities but instead are associations of plants, which exist nowhere else, brought together and maintained by humans, often women. They are convenient for procuring plant products, for their high productivity, and

for their great diversity of utilitarian species. Gardens may consist of native species alone, domesticated plants, or a mixture of both categories.

Wild versus Domesticated Plants

Wild or domesticated is a difficult distinction. Most plants have been selected for by many cultivation techniques. Few have avoided these human-induced life-cycle alterations to be called truly “wild.” Agricultural plants, on the other hand, have been selected for features useful to people. Their new genetic expressions are plant “artifacts” that do not exist in nature and probably would not reproduce without the assistance and habitat maintenance by people. Domesticated plants are found in all temperate and tropical continents except Australia. They include annual plant seed foods (wheat, barley, rice, millet, maize), vegetables (tomatoes, potatoes, onions, squash, spinach, cabbage), herbal spices (chilies, coriander, parsley), perennial tree fruits (apples, peaches, mangos) and nuts (walnuts, coconuts), and beverages (coffee and tea). People also domesticated utilitarian plants (bottle gourds, cotton, hemp). Each requires a beneficial habitat for growth, and people determine these. In arid lands, irrigation canals and lithic mulch fields are necessary to conserve water for plants. Examples are found in Arizona, Israel, India, and China. The soil is improved with the addition of animal manure and kitchen waste. Heat and the impact of direct sunlight are mitigated by intercropping shade plants with tea, coffee, and fruits. Stone terracing to create more arable land surface alters topography in Peru, Mexico, and China. Women often maintain gardens for culinary variation, dietary supplements, or the aesthetics of flowers. Small fields are maintained for subsistence and are weeded according to local cultural rules of plant use. Large fields are cleared for staple crops or for surplus to sell in markets.

Ethnobotany of Environmental History

Ethnobotany tracks the actions of people, guided by their belief systems, to learn about alternative

management techniques, and to understand how plant worlds are manipulated by different cultures. People use many techniques to secure a harvest of utilitarian plants. They have many management principles that regulate exploitation through scheduling their harvest activities, rotating collection areas, and limiting access by applying social and religious sanctions. These practices may benefit individual species and, simultaneously, increase habitat diversity through communities at different stages of plant succession and diverse landscapes of more productive plant associations.

The domestication of maize (*Zea mays*) and its methods of production present an example of the ethnobotany of environmental change. Maize is an artifact, created throughout human selection of phenotypic traits, which cannot reproduce without

human assistance. To grow it humans must eliminate plant competition by clearing the land and providing the environmental qualities required for growth, mainly control over water and temperature. By clearing the land a habitat is created for ruderals, like pigweed (*Amaranthus*) or lamb's quarters (*Chenopodium*), which can be eaten as leaves and seeds by farmers or weeded according to cultural practices. After the field is abandoned, new plants volunteer that might be useful as well and create successional patches of diverse plants and animals. None would occur in nature without human manipulation of the environment for cultural purposes.

Ethnocentrism

Ethnocentrism, the tendency to place one's own tribe, race, or country at the center of human affairs as superior to others, can be exemplified by the Western colonialism of the past five hundred years. But ethnocentrism is hardly limited to the West; it can be found throughout the world in other cultures' attitudes toward religious, racial, linguistic, and ethnic groups.

Ethnocentrism has existed in virtually all societies in human history. To feel superior to other peoples requires that one is aware of others beyond one's national or cultural boundaries. To feel superior to other peoples also requires that one knows enough about others to judge their civilization or way of life as inferior to one's own. Therefore, for ethnocentrism to take root and flourish, engagement with the world outside is necessary. A society that lacks the economic, military, or human resources to step outside its borders and do business with other peoples, whether through trade, conquest, or otherwise, cannot easily be labeled "ethnocentric," even if it is concerned primarily or solely with itself.

During the last two centuries Western colonialism placed much of the globe under the control of European countries or their transplants. Along with the political and military dimensions of colonialism, the colonizers often took it upon themselves to "improve" the subject peoples on the assumption that Western cultural values and social structures are superior to those of the subject peoples. The nineteenth-century English politician Thomas Macaulay justified, for example, the "anglicizing" of India on the grounds

that "one shelf of a Western library" had more to offer than centuries of Eastern knowledge and literature. French colonizers regarded *la mission civilisatrice* ("civilizing mission," the weaning of the natives from their primitive ways) as an integral part of their work in their colonies. Ethnocentrism certainly provided Europeans with a handy justification for their policies. Darwinist ideas during the late nineteenth century provided an argument to those people who believed that only the best, which generally meant their own nation, would survive and prosper over all others.

Ethnocentric worldviews have not, however, been limited to European colonists in the modern era. The Chinese name for their country, the Middle Kingdom, encapsulates the historical perspective that all those people outside its borders were barbarians who lacked the skills and civilization of the Chinese. This perspective applied to the numerous tribes of Central Asia, most famously the Mongols, whom the Chinese regarded as a constant threat to their way of life. When the British came to China during the eighteenth century to trade, and their emissary George Macartney refused to kowtow to the emperor, clearly strong feelings of ethnic superiority existed on both sides. Chinese attitudes changed, however, during the nineteenth century as the country was subjected to military defeats and humiliating treaties, and Chinese intellectuals sought to introduce Western-style reforms and openly acknowledged the inadequacy of traditional Chinese ideas in dealing with the challenges at hand. Ethnocentrism is dependent on the power that a certain group exercises in regard to others.

This drawing, in which the Scottish missionary David Livingstone shows off his pocket watch to curious Africans, conveys the ethnocentric notion of Western superiority.

Ethnocentric views need to be asserted and displayed to those who are being looked down upon.

East and West

The discussion of ethnocentrism has taken a new turn during the last two decades with the appearance of the Palestinian scholar Edward Said's ideas on Orientalism (an ethnocentric Western regard of Asian peoples) and the subsequent application of these ideas to areas beyond the scope of Said's study. Western knowledge of and attitudes toward non-Western peoples, according to Said, have been linked to Western dominance and power, both during the colonial era and after. Western representations of the East have been, his argument goes, both the cause and the result of the unequal power relationship between the

two during the last two hundred years. The East has been depicted as irrational, despotic, and backward in contrast to the rational, democratic, and progress-oriented West. Ethnocentric and racist attitudes have certainly played a role in this depiction. Although the point of Said's accusations has been widely acknowledged in scholarship and efforts have been made to rectify it, Orientalism arguably continues unabated in the news and popular media.

Although most people would regard ethnocentrism as undesirable, its close derivatives, such as nationalism, are often viewed positively. The explanation for this difference lies in part in the conflation (fusion) of ethnocentrism and racism, with racism clearly being a negative trait. Nationalism, on the other hand, does not always imply a race-based affiliation, although it, too, limits itself to a certain group to the exclusion of all others.

Ethnocentrism does not, however, always require an international context. Within the borders of a state, one racial or cultural or religious group can exercise power over others. Although European or white domination over others comes immediately to mind, this is by no means the only example. The disenfranchisement or even persecution of religious, linguistic, and ethnic minorities is widespread in both Western and non-Western countries in the modern world. Although this phenomenon is often not called "ethnocentrism," mainly because it is occurring within the same "people," its characteristics and impact are not very different from those of ethnocentrism in an international context.

Multiculturalism

Today people see multiculturalism, whether voluntary or encouraged or required by a government, as a desirable attitude in dealings with members of other groups. It denotes an openness to and appreciation of other cultures. Multiculturalism, so defined, is the opposite of ethnocentrism. Multiculturalism is not a purely twentieth-century phenomenon. It was a component, perhaps by a different name, of the

One thing is certain . . . we are not going to get any officer commission in the British or native army . . . The reason is that no Britisher would ever like to be under an Indian's command at present. It will require some generations before this feeling of the conquerors and the conquered, the ruler and the ruled, and of blacks and whites will fall away. • **Kunwar Amar Singh**

worldview of Romantics (proponents of a literary, artistic, and philosophical movement originating during the eighteenth century) such as the German philosopher and theologian Johann Herder, who respected and valued all cultures around the world, including “native” cultures that were evidently not at the same stage of historical development as those of the West. Multiculturalism in this case coexisted with a clear sense of being “above” certain other groups. Although modern multiculturalism is directed against biases, prejudices, and negativity toward other cultures, ethnocentrism, as an instinctual tendency to band together with people like oneself, may be hard to eliminate by social policy or decree. Perhaps the best hope lies in the interconnections and cross-cultural contacts that increasingly define our world and force us to recognize how critical members

of other groups are to our own physical and even cultural well-being.

Ethnology

Ethnology is a subtopic of anthropology that studies cultures around the world through comparison and analysis. Also known as cross-cultural research, ethnology developed over the latter twentieth century to focus on universal theories and broad generalizations that emphasize similarity rather than diversity across cultures.

Comparative ethnology (cross-cultural research) is a subfield of cultural anthropology. Anthropologists, psychologists, and sociologists who conduct cross-cultural research are interested primarily in developing and testing theories of human culture, society, and behavior by comparing the behaviors and customs of cultures around the world. The focus is on universal theories that explain all or some aspect of culture or behavior in all places at all times, rather than theories whose explanatory reach is only a single culture or a single geographic or cultural region. Cross-cultural research is similar to cross-national research (practiced mainly by political scientists and economists), which uses modern nation-states rather than cultures as its unit of study.

Cross-cultural research emerged as a distinct form of anthropological research during the late nineteenth century but did not garner much attention until the 1940s. By then a large quantity of ethnography (information on cultures and ethnic groups) had been gathered for hundreds of cultures around the world, providing the raw data for cross-cultural study. In the typical cross-cultural study, a researcher sets forth a theory or theories to be tested, selects a sample of cultures from around the world to be studied, collects information on the topics of interest

from ethnographic reports on the cultures, converts the textual information to numeric codes of variable value, and then uses statistical tests to test the theory or theories.

With more and more ethnographic data available in the decades after World War II, cross-cultural research became more popular, with several hundred studies on kinship, child development, family life, war, religion, economics, and politics published during the 1960s and 1970s. These two decades were also a period of maturation for the field as many new research techniques were developed to make for more careful research and more trustworthy results. Among the pioneers in the field were the anthropologists George Peter Murdock at Yale, Harold Driver at Indiana University, Raoul Naroll at State University of New York at Buffalo, and John and Beatrice Whiting at Harvard. During the 1980s, as cultural anthropology became more focused on specific cultures, on the study of meaning, and on action research to assist and protect endangered peoples, cross-cultural research declined in popularity.

Cross-cultural research has always been controversial; many anthropologists who prefer intensive field research in a single culture are uncomfortable with an approach based on library research, the use of secondary data, and statistical analysis, which tend to produce broad generalizations that emphasize similarity rather than diversity across cultures.

Nonetheless, several decades of cross-cultural research have produced a number of important generalizations, especially significant for world history: (1) About 50 percent of cultural change around the world during the last two centuries can be attributed to peaceful interaction between different cultures

and about 50 percent to contact through warfare and domination. (2) The type of economy in a society is an important determinant of how parents raise their children and of adult personality. For example, in agricultural societies where cooperation is important, people will be more compliant, and they will raise their children to be obedient. In foraging societies where independent action is valued, adults will be more independent and will raise their children to be self-reliant. (3) Cultural evolution has been a powerful force in human history, with more efficient control of energy and a larger population typically leading to specialization and differentiation in the institutions of a society. (4) Maintaining a large military force to deter enemies or potential enemies more often produces war than peace. Peaceful contact such as through trading or participation in joint religious rituals more often produces peace. (5) From a cross-cultural perspective, there is no such thing as “female status.” Rather, female status is a complex set of beliefs and behaviors, with women often having high status and much influence in some domains such as the household economy or religion, and little status and influence in other domains such as the military. (6) Ethnocentrism, the belief that one’s culture is superior to all others, is found in all cultures. It tends to be less pronounced among neighboring cultures that are similar in many ways. (7) All societies have a basic economic concern with control over and access to natural resources. (8) All societies have a clear division of labor by sex, with some work assigned exclusively to men and other work to women. Men tend to do work that requires much strength, whereas women tend to do work that is compatible with child care.

(9) Although egalitarian (relating to human equality) societies have existed, in the modern world all societies are socially stratified, often into social classes, meaning that not all groups have equal access to a society’s resources. (10) A considerable amount of radical cultural change throughout history is the result of religious movements. These movements often develop in times of societal stress and are led by charismatic figures often defined as prophets. (11) The evolutionary ideas of the nineteenth century that suggested that human society evolved through time from a state of lesser to greater civilization have no merit.

Eurasia, Inner

Inner Eurasia typically refers to a huge area that includes all the lands within the former Soviet Union, as well as Mongolia, Xinjiang, and Inner Mongolia. The region's flatness explains the expansiveness of the countries found there; it also clarifies the dominant role of pastoralism and nomadic societies that have shaped the history of the area from the foraging era to the present day.

Innor Eurasia is one of several geographical labels that can be used when thinking about the history of the interior regions of Eurasia. Other labels that refer to the innermost regions of the Eurasian land-mass include Turkistan, Inner Asia, Central Eurasia, and Central Asia. The label Inner Eurasia is the most inclusive of all the alternatives, linking the fate of Central Asia to that of the lands included within Mongolia and the former Soviet Union, and suggesting that the history of this entire region was shaped by the distinctive geography of the Eurasian heartlands.

Using geographical labels with care and precision is a matter of great importance within all forms of history, but particularly within world history, for geographical labels shape how we think about the past and help steer historical arguments along particular trajectories. Used uncritically, they can warp our accounts of the past, projecting present-day assumptions into the remote past. Used carefully and critically, they can reveal new aspects of the past. As the geographers Martin Lewis and Karen Wigen have argued, metageographies, or the categories we use to think about the geography of the world, shape historical arguments at the most profound levels. For example, the conventional division of Europe and Asia at

the Ural Mountains carries the implicit assumption that Eurasia divides naturally into its European and Asian components, that all Asian societies share basic similarities, and that a line from the Urals to the Black Sea constitutes the fault line between these metaregions. None of these assumptions bears serious scrutiny today, yet the labels persist as traps for the uncritical reader.

Delineating Inner Eurasia

Inner Eurasia refers to a huge area that includes all the lands within the former Soviet Union, as well as Mongolia, Xinjiang, and Inner Mongolia. To group this large and disparate region together makes sense only on the hypothesis that Inner Eurasia has an underlying geographical coherence that has shaped the history of the entire region. Early in the twentieth century, the British geographer Halford Mackinder argued that it is helpful to think of the Eurasian land-mass as divided into two main regions. At its heart is a huge, largely flat, plain—the largest continuous region of flatlands on Earth. Inner Eurasia was constructed mainly from two ancient tectonic plates (the Siberian plates) that joined some 300 million years ago to create a huge mountain chain that has since worn away to leave the low Ural Mountains. Attached to the west, south, and east of the Inner Eurasian plain lie several subcontinental peninsulas, all with a more varied topography. These make up what we can call Outer Eurasia. Outer Eurasia includes Europe and southwest Asia, the Indian subcontinent, Southeast Asia, and China. The plates carrying modern Europe and China joined the Siberian plates approximately 200 million years ago. Within the last 60

million years, the plates carrying modern India and Africa drove north and collided with the Eurasian plate, creating a chain of mountains from the Alps to the Himalayas. These offer the clearest topographical border between Inner and Outer Eurasia. So, at the most general level, Eurasia consists of an ancient, interior plain that is surrounded by regions closer to the sea that have a choppier and more complex topography.

On large scales, Inner and Outer Eurasia are very different. Not only is Inner Eurasia mostly flatter than Outer Eurasia, it is also more arid, for it is cut off from the sea, except to the north where extreme cold limits evaporation and precipitation. In Inner Eurasia, average yearly rainfall exceeds 50 centimeters only in the far west (in modern Belarus, northern Ukraine, and European Russia), along the southern parts of the eastern Siberian coast, and in pockets in Siberia; in Outer Eurasia, regions with rainfall of less than 50 centimeters a year are unusual, and in many regions average rainfall is well above 100 centimeters a year. Because it lies further north, there is less sunlight for photosynthesis. Inner Eurasia is also, on average, colder than Outer Eurasia. As Mackinder (1962, 110) pointed out, the heartland of Eurasia is, roughly speaking, the part that freezes in January: “At mid-winter, as seen from the moon, a vast white shield would reveal the Heartland in its largest meaning.” Because Inner Eurasia is so flat and most of it is far from the moderating influence of oceans, its temperatures also tend to be more extreme than those of Outer Eurasia. Differences between summer and winter increase as one moves east, so that, in general, the climates of Mongolia are harsher and more variable than those of Ukraine.

Flatness, aridity, northerly latitudes, and continental climates shaped all the societies of Inner Eurasia and ensured that the history of Inner Eurasia would be very different from that of Outer Eurasia. Flatness explains why the states that emerged in this region were some of the largest in the world, for there were few geographical barriers to the movements of powerful armies. The harsh climatic and ecological environments of Inner Eurasia help explain why population

densities were lower than in most of Outer Eurasia. This was true even in the foraging (Paleolithic) era, for humans evolved in the savanna lands of Africa and had to develop entirely new forms of clothing and housing, as well as new hunting techniques, to settle in Inner Eurasia. In the last two thousand years, the populations of Inner Eurasia have varied from one-tenth to one-twentieth of those of Outer Eurasia, even though the two regions are approximately the same size. Given these difficulties, it is not surprising that Inner Eurasia seems to have been settled later than most of Outer Eurasia. In the Neolithic era, the region’s aridity ensured that agriculture made little headway for many thousands of years, except in parts of modern Ukraine and in the borderlands of Central Asia, where irrigation farming was possible. Extensive farming communities appeared in the so-called Tripolye culture of Ukraine, and in Central Asia, significant urban communities emerged during the third millennium BCE. Elsewhere, the Neolithic revolution in its most familiar form, that of grain-based agriculture, bypassed most of Inner Eurasia. So, while agriculture spread in much of Outer Eurasia, laying the foundations for several great agrarian civilizations, in Inner Eurasia agriculture made hardly any headway for many thousands of years. Instead, Neolithic technologies entered Inner Eurasia in the less familiar form of pastoralism.

Pastoralism

Unlike agricultural lifeways, which are dominated by domesticated plants, pastoral lifeways are dominated by the exploitation of domesticated livestock. Pastoralism became a viable lifeway as a result of a series of innovations that the archaeologist Andrew Sherratt has described as the secondary-products revolution. Beginning around 4000 BCE, people began to exploit not just those products of livestock that could be used after an animal’s slaughter (its skin, bones, and meat), but also the animal’s secondary products—products such as its wool, blood, milk, and traction power—that could be used while it was still alive. These techniques raised the efficiency with which domesticated

The peoples of Inner Eurasia used a variety of animals for transport. This photo from the early twentieth century shows camels loaded with fodder.

animals could be exploited, making it possible to build entire lifeways around the use of domesticated animals such as sheep, cattle, goats, horses, camels, and yaks. Pastoralism proved an effective way of exploiting the vast grasslands that stretched from Hungary to Manchuria, and, for several thousand years, it was the dominant lifeway throughout this region. The earliest evidence of pastoralism comes from the Sredny Stog cultures of eastern Ukraine, which include some of the first evidence for the riding of horses. These were still relatively sedentary cultures. But in the third millennium BCE, pastoralism of some form spread throughout much of southern Russia and Ukraine and into parts of modern Kazakhstan. Evidence from steppe burial mounds suggests that pastoralism was also becoming more nomadic, and this makes ecological sense, for the most economical way to graze large numbers of animals is to move them over large areas. By 2000 BCE, pastoralism of some form had spread towards the western borders of Mongolia. Nicola Di Cosmo, a specialist on Inner Asia, writes, “A conservative interpretation would date a significant impact of horseback riding on western and Central Asia to between the mid-third and early second millennium BCE” (2001, 26). In the

first millennium BCE, pastoralism finally spread to Mongolia. It also appeared in new and more warlike forms that may have depended on technological innovations such as the appearance of new and improved saddles and improved compound bows.

The dominant role of pastoralism in the steppes of Inner Eurasia had a profound impact on the history of the entire region, and also on the way that the region’s history has been perceived. Pastoralism cannot support the large populations that agriculture can, and pastoralists are normally nomadic or seminomadic, so pastoralism did not generate the areas of dense settlement characteristic of so much of Outer Eurasia. For the most part, this was a world without towns or cities. Instead of villages and cities, small, nomadic encampments dominated the steppes. Because cities and all the paraphernalia we associate with cities and agrarian civilizations existed only in a few borderland regions of Inner Eurasia, the history of the region was strikingly different from that of Outer Eurasia. For the historian, one of the most important differences is that pastoralist societies generated few written records. Because historians rely heavily on such records, they have tended to ignore societies that do not produce them. So Inner Eurasia has too

Camels can easily transport yurts—portable, wood lattice-framed structures covered with felt—across the steppes. Thus the yurt became the optimum dwelling for both nomads and pastoralists.

often been seen through the eyes of the agrarian civilizations of Outer Eurasia, beginning with the works of the Greek historian Herodotus (c. 484–425 BCE) and the Chinese Han dynasty historian Sima Qian (c. 145–86 BCE). Even the most sympathetic Outer Eurasian historians portrayed Inner Eurasia as a sort of black hole out of which pastoralists rode to rape and pillage the villages and cities of the “civilized” world. Not surprisingly, Inner Eurasian pastoralists have traditionally been cast as “barbarians” in world historiography.

In part, this is because the mobility of pastoralism, the skills it teaches in the handling of large animals, and the ubiquity of raiding ensured that most pastoralist societies of Inner Eurasia have had a military influence out of proportion to their sheer numbers. In a famous passage, Sima Qian wrote of the pastoralist Xiongnu to China’s north:

The little boys start out by learning to ride sheep and shoot birds and rats with a bow and arrow, and when they get a little older they shoot foxes and hares, which are used for food. Thus all the young men are able to use a bow and act as armed cavalry in time of

war. It is their custom to herd their flocks in times of peace and make their living by hunting, but in periods of crisis they take up arms and go off on plundering and marauding expeditions. (Watson 1961, 2:155)

The limited resources of pastoralist societies also ensured that they were usually keen to engage in exchanges with neighboring communities of farmers, trading livestock produce such as meat, skins, and cloths for agricultural products and artisan goods including weaponry. Evidence of such exchanges, some peaceful, but some clearly violent, appears as early as the fourth millennium BCE on the edges of the Tripolye culture in Ukraine, in the objects found within steppe burial mounds and in the increasing use of fortifications by farming communities.

Inner Eurasia and Cultural Exchange

The mobility of pastoralists and their interest in exchanges ensured that goods, ideas, people, and influences passed much more readily through the Inner Eurasian steppes than is commonly supposed. Pastoralists carried the technologies of pastoralism

through the steppes to the borders with China. They also carried languages. The Indo-European languages spread throughout southern Inner Eurasia and then beyond, carried largely by communities of pastoralists, while Turkic languages began to spread eastwards from about 2,000 years ago, also carried mainly by pastoralists. In addition, pastoralist communities helped spread religious practices and artistic motifs, as well as technologies such as bronze working and the use of chariots. The Inner Eurasian steppes, far from being a barrier to civilization, provided the interconnections that from at least the second millennium BCE ensured that the history of the entire Eurasian landmass would have a certain underlying unity, nurtured by the symbiotic relationship between the societies of Inner and Outer Eurasia.

The existence of trans-Eurasian contacts is evident as early as 2000 BCE within the Oxus civilization (on the borders of modern Afghanistan, Turkmenistan, and Uzbekistan), where archaeologists have found goods from the steppes, as well as goods from Mesopotamia, India, and even China. The importance of trans-Eurasian exchanges increased in the first millennium BCE when, for the first time, Outer Eurasian states, including Achaemenid Persia and Han China, tried to conquer parts of Inner Eurasia, and trade goods, including silk, started to flow right across Eurasia. The modern term *Silk Roads* is used to refer to the networks of exchange through Inner Eurasia that linked all parts of the Eurasian landmass.

Inner Eurasian Pastoralist States

The military power of pastoralist communities meant that when they were threatened, they could unite quickly to form powerful military confederations that were a match for the armies of great Outer Eurasian powers. The military power of such confederations was first realized clearly in the agrarian world when pastoralist armies defeated and killed Cyrus II (reigned 558–529 BCE), the founder of the Achaemenid Empire, but it is also apparent from the detailed account by Herodotus of the unsuccessful campaign in the Black Sea steppes of Cyrus's successor, Darius I

(reigned 522–486 BCE). In the second century BCE, for the first time, a pastoralist leader managed to build a confederation of pastoralists and hold it together long enough that historians conventionally refer to it as a state or empire. This was the achievement of Modun (reigned 209–174 BCE), the creator of the Xiongnu Empire in modern Mongolia.

Inner Eurasian pastoralist states were very different from the agrarian and city-based states of Outer Eurasia. With limited human and material resources, they could be held together only by extracting resources from neighboring agrarian regions using a complex mixture of looting, tribute taking, taxation, and trade, and redistributing them to regional chiefs. So, as Thomas Barfield and Nicola Di Cosmo have pointed out, the success and longevity of pastoralist empires depended on how well they could accomplish that task. The larger the flow of material and cultural resources, the more powerful the state, so it is no accident that the most powerful pastoralist states, such as the sixth-century Turkic Empire and the empire of Chinggis (Genghis) Khan in the thirteenth century, were built by extracting resources from powerful agrarian states such as China or Persia. This also explains why major pastoralist states appeared along the border regions between Inner Eurasia and Outer Eurasia, and why many powerful pastoralist leaders, including the Seljuks in the twelfth century and the Mughals in the sixteenth century, eventually crossed the border to found dynasties in nearby regions of Outer Eurasia.

Agriculture in Inner Eurasia

The dominant role of pastoralism in Inner Eurasia created a complex symbiotic relationship across the borders between Inner and Outer Eurasia for several millennia. But in the last thousand years, the dominance of pastoralists in Inner Eurasia has been challenged by the spread of agrarian communities from the west. In the middle of the first millennium CE, large numbers of peasant farmers from eastern Europe began to settle in the lands west of the Urals that are dominated today by Belarus, Ukraine, and western

Russia. Why farmers should have settled this region after avoiding it for several millennia remains unclear, though it may have something to do with the cultivation of rye and the increasing use of metal implements, which made farming more viable even in the difficult climatic conditions of western Inner Eurasia. Steppe rulers such as the Khazars (flourished seventh to tenth centuries) began to extract resources from these communities, but it was Viking warriors who established the first durable agrarian states in the region, with the formation of a federation of city-states, united under Viking leaders, some time in the tenth century.

As agriculture spread within Inner Eurasia, it became an increasingly important foundation for emerging states, providing a demographic and economic basis that no pastoralist communities could match. Agriculture sustained the power not just of Rus and Lithuania, but also of remnant states of the Mongol Empire, such as the Golden Horde (thirteenth to fifteenth centuries). Eventually the state of Muscovy established control of most of the agrarian lands of western Inner Eurasia, and over the next few centuries it built the largest agrarian state in the world as it slowly established its control over the woodlands of Siberia. The greater demographic dynamism of agriculture ensured that, over time, the sheer numbers of people supported within agrarian states would give them an advantage over neighboring pastoralist societies as well, and so, over many generations, Muscovy and the Russian Empire also began to encroach on the steppes of Inner Eurasia. By the end of the nineteenth century, the Russian Empire had conquered most of the steppes and all of Central Asia. Meanwhile, the Qing dynasty (1644–1911/12) in China had conquered Xinjiang, after defeating the last great pastoralist empire, that of the Dzhungars, and established its control over much of Mongolia. The dominance of pastoralism had ended and Inner Eurasia, like Outer Eurasia, was now dominated by agrarian states.

The distinctive geography of Inner Eurasia, however, left its mark even on the now-dominant agrarian states of the region. The ecological difficulties of Inner Eurasia ensured that agriculture was never easy and rarely as productive as in most of Outer Eurasia. As a result, the agrarian states of Inner Eurasia had to

be peculiarly good at mobilizing resources, and that meant they needed strong, autocratic leadership. At the same time, the flatness of the steppes exposed both agrarian and pastoralist states to almost constant border conflict and forced them to concentrate resources to a peculiar degree on warfare. But it also made it possible to build huge states, for geography posed few natural barriers to the expansion of powerful states. This is why the history of Muscovy and Russia can be thought of as a slow filling up of the lands of Inner Eurasia. Finally, the mobilizational traditions of Russian states, dictated by the relative ecological poverty of Inner Eurasia, may help explain why, in the Soviet era, there emerged an economy and society very different from those of the capitalist West. Soviet society, like the society of Muscovite and Imperial Russia, was dominated by a powerful autocratic state capable of mobilizing resources with exceptional intensity. In this way, the distinctive features of Inner Eurasia's geography have shaped the region's history from the foraging era to the present day.

Eurocentrism

Eurocentrism, simplistically, puts Europe at the “center of the universe.” It interprets the world through Western values but should more accurately be termed Western-centrism since it incorporates Europe as well as the cultures of North America and Australia. Although it has existed in varying degrees for centuries, it was fortified by the physical and economic power of the twentieth century, which increased its presence around the world.

The writer Neal Ascherson suggested that “on the shores of the Black Sea were born a pair of Siamese twins called ‘civilization’ and ‘barbarism’” (1995, 49). The observation about these twins is surely incisive and universal, even if the Black Sea venue may be questioned. The civilized and barbarian twins have had many births and rebirths in all times and places occupied by people. Moreover, they have ever been co-terminus with centrism—Greco-, Islamic-, Sino-, Euro-, U.S.-, Western- and many others—each of which labeled all others barbarians. What distinguishes Eurocentrism (actually Western-centrism, since Eurocentrism incorporates such geographically disparate regions as North America and Australia as well as Europe) is that during the past century or more it has been accompanied by power, which it has used to legitimate, extend, and maintain itself and its rule in the world.

In 1978 the literary critic Edward Said condemned “Orientalism”—Western conceptions of the Islamic world—as a grab bag of ill-defined characteristics that are distinctive only in allegedly being non-Western. Indeed, the very invention of

Orientalism was not so much an attempt to say something about “the Orient” as an attempt to delineate and distinguish “the West” from “the rest,” as the scholar Samuel Huntington put it in his 1993 article “Clash of Civilizations” in the journal *Foreign Relations*. The media immediately welcomed this formulation of an alleged clash between the West and (in particular) China and Islam; and they have even more widely accepted it as an explanation of world events since the terrorist attacks of September 11, 2001. However, Gernot Köhler, a scholar of international relations and the world economy, has suggested that the sort of thinking that leads to Orientalism or to theories of civilization clashes goes hand in hand with the notion of global apartheid: the first is an ideological facet of the second, just as the notion of the “white man’s burden” was an ideological facet of European colonialism and imperialism.

Nor does it appear that the decolonization of the second half of the twentieth century has put those notions to rest in the sands of history. On the contrary, the rhetoric of such former leaders as Britain’s prime minister Tony Blair (served 1997–2007) and the U.S. president George W. Bush (served 2001–2009) is replete with claims that they were defending civilization (with the unspoken assumption being that they meant Western civilization) against outside threats—this in spite of the fact that many argued that some of their methods, such as Bush’s doctrine of preemptive war, threatened to destroy one of civilization’s most precious gifts: international law and institutions to prevent man from killing man in a general war of all against all.

Historical Development of Eurocentrism

Eurocentrism currently exerts widespread influence in the humanities, social sciences, and even the natural and physical sciences, but it was not always so. The 1911 edition of the *Oxford Dictionary of Current English* defined *orient* as “The East; lustrous, sparkling, precious; radiant, rising, nascent; place or exactly determine position, settle or find bearings; bring into clearly understood relations; direct towards; determine how one stands in relation to one’s surroundings. Turn eastward.” By 1980, however, the *American Oxford Dictionary* defined it simply as “The East; countries east of the Mediterranean, especially East Asia.” The Orient as a model to be acclaimed and copied had become the antimodel to be defamed and shunned. Such European luminaries as the philosopher René Descartes (1596–1650), the writer Voltaire (1694–1778), and the economist Adam Smith (1723–1790), however, were still persuaded by the former definition.

Although the French intellectual Montesquieu (1689–1755) was an early forerunner of the change to a more negative image of the East, the major transformation in opinion came with the European Industrial Revolution and colonialism, especially from the mid-nineteenth century, with those proponents of dialectical change, G. W. F. Hegel (1770–1831) and Karl Marx (1818–1883). Their total Eurocentrism really did turn views of the world on its head. They began a tradition in the humanities and social sciences of differentiating the progressive “us” from the traditional “them” that continues to this day. Historiography—even “world” history—in the West has been entirely Eurocentric, running only on a westward track from “the Orient” to Western Europe and America. Works in this vein include the uncompleted *Weltgeschichte* (Universal History) of Leopold von Ranke (1795–1886), the twelve-volume *Study of History* (1934–1961) of Arnold Toynbee (1889–1975), who described the rise and fall of twenty-one “civilizations” and the “arrested development” of five others, and William H. McNeill’s *Rise of the West*, originally

published in 1963. Nor is the history of science immune from a focus on the West: the very notion of a seventeenth-century scientific revolution in Europe that is taken to be the basis of Europe’s technological and industrial revolution tends to downplay scientific innovation or contributions from other parts of the world.

Eurocentrism in Sociology and Anthropology

From the 1850s this dichotomy of the West and the rest and attendant praise of things Western has been the hallmark of all Western social theory. The nineteenth-century French “father of sociology” Auguste Comte (1798–1857) and the British legal scholar Henry Maine (1822–1888) distinguished between European “science” and “contracts,” which allegedly replaced age-old “tradition.” The French sociologist Émile Durkheim (1858–1917) distinguished “organic” and “mechanical” forms of social organization, and the German sociologist Ferdinand Tönnies (1855–1936) alleged a transition from traditional *gemeinschaft* (“community”) to modern *gesellschaft* (“society”). In the twentieth century the sociologist and economist Max Weber (1864–1920) considered European rationality to be the essential ingredient in Western success, as described in *The Protestant Ethic and the Spirit of Capitalism* (1904–1905). During the Cold War, the sociologist Talcott Parsons, who popularized Weber in the United States, distinguished Western “universalist” social forms from the “particularist” social forms of other cultures, and the anthropologist Robert Redfield found a contrast and transition between traditional “folk” and modern “urban” society and a certain symbiosis between “low” and “high” civilizations. In each case, the modern, progressive, “good” side of the dichotomy is the Western one, and the other is the “Orientalist” one, which the Palestinian American Edward Said condemned as an invented grab bag of whatever is not “Western.” The modernization theory that dominated postwar social sciences and economics distinguished Western modernization

Europe was created by history. America was created by philosophy. • Margaret Thatcher (b. 1925)

from other cultures' and regions' traditionalism. The economist W. W. Rostow's *Stages of Economic Growth* (1959) was a major vehicle for articulating modernization theory and followed the same Eurocentric theoretical path from traditional to postindustrialist society. As late as 1998, David Landes' best-selling *The Wealth and Poverty of Nations* assured readers of the exceptionality of European culture.

Twenty-First Century Eurocentrism

In its present incarnation, critics of Eurocentrism believe it entails the successful, free-trading West teaching the rest of the world the merits of a “pull-yourself-up-by-your-bootstraps ethic,” which will, its Western proponents believe, bring the wealth of the West to the poor rest. The harshest critics of Eurocentrism see this formulation as an oxymoron. If the idea is to “pull yourself up by your own bootstraps,” as the Eurocentrists claim, then what happens to the theory that the rest of the world is supposedly being saved by Western beneficence? The worst forms of Eurocentrism, its critics believe, received a new lease on life after September 11, 2001 by the George W. Bush and Tony Blair propaganda machine, which never tired of claiming to be dropping their bombs to “Save [Western] Civilization.” The media that supported this machine trumped up Samuel Huntington's alleged

clash of civilizations between “the West” and “the Rest”—and particularly against Islam and China.

Europe

Europe as we know it has evolved over centuries, shaped by its history, wars, empires, neighbors, and encounters with different peoples and cultures, both near and far. Today Europe is considered a continental home, but the notion of a European continent was not born until the sixteenth century. It has few natural boundaries and it defined more by its relations with other regions than by its geography.

Europe was an idea long before it acquired anything like its present geographical contours, internal structures and relationships, or connection to the rest of the world. The idea of a European continent may seem to belong to the natural order of things, but the idea of a continent is relatively modern, dating from the sixteenth century. Europe belonged to the realm of myth before it acquired a concrete physical location. The name comes from Greek myth, the story of Europa. In that story, Europa, the daughter of a Phoenician king, is abducted and raped by the Greek god Zeus. He takes her from her home on the Asian coast of the Mediterranean to Crete, where she bears three sons, giving birth to Minoan civilization. As a mother figure, Europa provided the Greeks, and later Europe itself, with a powerful myth of origins. But Europe did not originally refer to the geographical space that now bears that name. It was originally attached to the Aegean coast and only gradually came to be attached to its northern and western hinterlands, to the areas we now associate with the Balkans.

The Greeks used other allegorical female figures, Asia and Africa, to name the lands to their east and south, thereby creating a tripartite division of the world, which they thought of as an island (Orbis

Terrarum) encircled by an impassable river, which they called Oceanus. Europe, Asia, and Africa were not originally conceived of as separate continents, but as parts of a single landmass. The Judeo-Christian myth of Noah's three sons also presents the idea of an earth island divided into three parts, each inherited by one of the sons, with Shem coming into the possession of Asia, Ham of Africa, and Japheth Europe. It was not until the existence of another landmass was established in the wake of the voyages of Columbus, and identified with another female figure, America, that the concept of continents came into being. When the ancient notion of Orbis Terrarum became obsolete, so did the idea of Oceanus. The idea of the encircling river gave way to the notion of several seas connecting the newfound continents.

Today Europe is one of seven recognized continents, though its claim to that status is not founded in physical geography. Europe is not surrounded by water and it lacks any clear natural boundaries that would differentiate it from Asia. From the beginning, Europe was a floating signifier, attached to a variety of territories, expanding and contracting in scale, changing meaning according to the purposes of those who defined it. As the historian Hugh Seton-Watson observed: "The word 'Europe' had been used and misused, interpreted and misinterpreted in as many different meanings as any word in any language. There are many Europes. . . ." (Wilson and van der Dussen 1993, 8).

Europe is by no means alone in this respect. Most continents are mythical in the sense that they are names given to geographies whose external boundaries are rarely self-evident and whose internal divisions may be greater than those between them and other landmasses. Names like Europe, Africa, and America

Titian, *The Rape of Europa* (1559–1562). Oil on canvas. Isabella Gardener Stewart Museum.

are very good at conveying meaning, but not very useful in revealing the actual boundaries of populations, economies, or cultures. It is with good reason that geographers such as Martin Wigan and historians such as Kären Lewis have recently begun to talk about the “myth of continents” as standing in the way of a better understanding of the world at large. Yet we are unlikely to see the concept of continents disappear in the near future. The term *Europe* remains a very powerful signifier despite the fact that it has changed content and meaning so many times over the centuries.

Ancient and Medieval Notions

Europe was only a vague geographical expression to the Greeks, who identified it with the neighboring

lands to their north and west, which were thought to share a similar climate and therefore whose people were thought to possess a civilized temperament conducive to self-government. The Greeks were fond of contrasting their own freedoms with the supposed despotism of their great enemies, the Persians, which by extension they attributed to all the peoples of Asia. Lands far to the north were thought to be cold and barbaric, while lands further south were considered too hot for human habitation.

The flexibility of the concept of Europe is due to the fact that it was not generated by any one state, nation, or culture. As was the case with the Americas and Australia, Europe was named by outsiders, one of the reasons the term has been so fraught with uncertainty and ambiguity ever since. Those peoples residing in

what the ancient Greeks called Europe did not know themselves as Europeans any more than the peoples living in Asia knew themselves as Asians or peoples of Africa called themselves Africans. They identified primarily with their locality. Even the Greeks did not think of themselves primarily as Europeans, for they identified with their particular city-states. They were Athenians and Spartans before they were Greeks,

much less Europeans. The term *European* was never used by them or by the Romans, another city-people who had no particular attachment to the territories that lay between cities. At the peak of Roman imperial expansion, the European, Asian, and African parts of the empire appeared to Romans to constitute the whole world. Identified with a language, a body of law, and a culture rather than a specific territory,

Europe seen by satellite on 13 November 2004. The name “Europe” originally pertained to the Aegean coast and only gradually came to be attached to its northern and western hinterlands, to the areas we now associate with the Balkans. NASA.

Rome saw itself as universal, a claim that was reinforced when its emperor declared Christianity to be the state religion in 313 CE. A world empire wedded to a world religion left no room for a separate European identity.

It was only in the wake of the collapse of the Roman Empire that what we now think of as Europe emerged as something more than a hinterland of the Mediterranean littoral. But the consolidation of this new Europe was slow in happening because, while the imperial state disappeared, the universal church did not. Europe remained a part of the larger entity known as Christendom, which included portions of Asia and Africa as well as Europe for the next several hundred years. Throughout the Middle Ages the ancient view of the world as an earth island surrounded by an impassable river held firm. Asia continued to be Christianity’s place of origin, and medieval Europeans continued to be spiritually and materially oriented toward the east, accounting for their designation of it as the Orient. Jerusalem was located on medieval world maps at the center of *Orbis Terrarum*. Asia, now open by way of the Silk Roads, was seen as a land of superior riches, while Africa too was the locus of European desires for gold and other luxury items. Europe itself was seen as peripheral.

During the Middle Ages Europe remained a geographical expression, without political unity, an economic center, or a strong sense of itself as a distinct civilization. Medieval Europe was anything but Eurocentric. Shown on its own maps as the smallest part of *Orbis Terrarum*, Europe saw itself as the western peninsula of Asia. Arabic maps of the Middle Ages showed it without distinct features, a reflection of how little it counted in the view of the great Islamic civilizations of the period. The Chinese, who viewed themselves as the center of the world, had no concept of Europe until European Jesuits introduced them to the idea in the late sixteenth century. Even then, they placed Europe on the margins of the Earth, a view shared by many Europeans of the time.

Apart from the Vikings, the peoples occupying that part of earth island known as Europe were not seafaring. They turned their backs to Oceanus and faced eastward spiritually and economically. When the Turks cut off overland access to the Orient in the fifteenth century, Europeans intensified their efforts to venture around Africa. Eventually they turned west to cross the Atlantic. It was only then, and very tentatively, that they began to think of themselves as Europeans. Not until they encountered one another overseas did Englishmen, Flemings, and Genoese begin to use the term “we Europeans,” as Francis Bacon did in 1620 CE. Only after establishing sea-based empires in the sixteenth century did Europeans reorient themselves from east to west. It was only then that they came to see history moving in a new direction. Christianity, born in Asia and nurtured during its first centuries in Africa, was for the first time seen as essentially a European faith. Henceforth, Europe would no longer subordinate itself to Christendom, but would define it. In the course of the sixteenth and seventeenth centuries Europe ceased to be a geographical expression and became a core region with its own peripheries. Having cut itself off from the Asian and African parts of the old Christendom, Europe emerged from the Age of Discovery smaller and more compact, but with an integral geography and a sense of itself both as a place and as an independent historical agent.

Europe Becomes a Continent

The notion of a European continent was born in the sixteenth century, but it took much longer before the peoples indigenous to it came to see themselves as Europeans. The idea of a secular Europe, as distinct from Christendom, first took hold among the elite classes. It arose in part out of balance-of-power diplomacy, which was itself a response to the religious wars of the seventeenth century, brought to an end by the Peace of Westphalia of 1648. While premised on the notion of internal division, thinking of Europe as a coherent system of competing territorial states—the origins of the Westphalian states system—was the first step toward separating it from the rest of the world. It took a much longer time for the idea of “European-ness” to trickle down to the lower classes, who were slow to exchange their local identities for national ones, and even slower to consider themselves Europeans.

But before Europe identified itself entirely with its continental geography, it saw itself as a civilization with boundaries that extended westward. European overseas expansion in the early modern period established the New World in the Americas, a series of what can be called “neo-Europes.” European settlers’ identification with the homeland was

so strong that it seemed in the eighteenth century that Europe might ultimately span the Atlantic. The conquest of Ireland was the first step in the construction of what the British saw as a greater Britain bridging the Atlantic. Spain established colonies in the Americas from the early sixteenth century onward; France and England established colonies there in the early seventeenth century. The colonial revolts of the later eighteenth century put an end to the idea of a pan-Atlantic Europe politically, but the imprint of European culture remained strong, encouraging the idea that it was, like Roman culture, universal, transcending geographical limits.

By the eighteenth century Europe identified itself with “civilization,” a term coined by the French politician Count Mirabeau in the 1750s. For the first time Europe shed its ancient sense of inferiority to Asia, especially to China. In the minds of Europeans, their culture had become the universal standard, available to all the world’s peoples willing to subscribe to its tenets. Defined initially as a loose package of values, techniques, and ways of life—the essence of the Enlightenment—the European concept of civilization became, by the nineteenth century, a kind of natural law of human progress, seen as spreading inevitably from Europe to the Americas and then to all the world.

In the nineteenth century Europe took on a clearer territorial definition, focused on its western regions. Following Napoleon's failure to impose continental political and economic unity, the thrust of the industrial and democratic revolutions in western Europe produced powerful economies within the boundaries of new nation-states. The evident differences between western European nations and the regions to the east and south became accentuated. Autocratic Russia now became Europe's "window on the East." During the New Imperialism of the later nineteenth century, Europeans' consciousness of their European-ness was again reinforced by encounters with non-European peoples, affirming the observation that "Europe did not simply expand overseas, it made itself through expansion" (Asad 2002, 220). European anthropology and ethnology supposedly gave scientific credence to Europeans' heightened sense of difference and superiority. Evolutionary conceptions of history, which organized the world's societies in terms of stages of development from savagery to civilization, reinforced Europeans' sense of being at the forefront of the march of progress.

In the eighteenth century Europe gained a geography; in the nineteenth century it acquired a history. The French Revolution had marked a decisive break with the past and triggered a quest for an historical

account that would provide Europeans with a sense of common origins. Political conservatives imagined the Middle Ages as laying the foundations of a unique European civilization, while radicals took Greek democracy as their starting point. The fact that neither the ancient Greeks nor medieval Christians would have recognized themselves as the first Europeans was no deterrent to this project. Despite the fact that both versions of the past were wholly anachronistic, they remain the favorite starting points for European history in schools and universities, distorting the past but providing a powerful myth of origins. Histories of Europe (and of the world) have tended to characterize it as being set apart from and superior to other world regions, cultures, and religions.

The notion of European superiority lost some credibility after the two world wars of the twentieth century, but the notion of one universal path of human development persisted. *Modernization*, a term more frequently used in the United States than in Europe, replaced *civilization* as the key word in the vocabulary of comparison. Although clearly biased toward Western interests and values, modernization was supposedly universal in character, knowing no geographical boundaries. Today, *globalization* is the term most frequently used to describe the supposedly

inevitable processes that will transform the whole world, erasing geographical boundaries and cultural differences. This is but the latest example of the universalizing tendency of European culture, now fortified by the wealth and power of the neo-European United States.

Contemporary Europe

There have been many Europes, and today we see yet another emerging. The entity that is unfolding before our eyes began as a core of western European nations defining themselves against the Soviet Union and its Communist allies. The Cold War division between West and East provided a powerful unifying factor, but since the collapse of Eastern European Communism beginning in 1989, Europe has had no obvious “other” to define its boundaries. Now that former Communist nations are joining the European Union, the boundaries of Europe are again in flux. Should Turkey become a member of the Union, the ancient boundary between Europe and Asia would also be breached, and the notion of absolute difference between the western freedom and eastern despotism would finally be renegotiated.

This is also a time when geographers and historians are reexamining the idea of the continent itself. After all, Europe has few natural boundaries and has always been defined by its relations with other world regions rather than by something internal to itself. What Europe means to Europeans has been inseparable from world history from the very moment that the Greeks adopted the origin myth of Europa to define themselves against the Persians.

It is therefore wholly appropriate that in this age of intense global interaction, when the identities of all the world's regions are being formed and reformed at their various points of contact, we recognize just how relative and contingent the notion of Europe has been from the very beginning. The accelerated speed of communications and travel has rendered old geographical boundaries largely obsolete, but it has by no means led to the abolition of a sense of difference. In

fact, the processes associated with globalization have accelerated the rate at which both internal and external differences are produced and institutionalized. These differences are less likely to be national than regional and subregional. Even as they construct a larger political-economic unit in the form of the European Union, Europeans seem to be moving toward a new localism, emphasizing indigenous languages, cultures, and traditions. Today's typical European has multiple identities, those of locality, region, nation, continent, and for some, the world at large. These are often in tension and can sometimes flare into conflict as has happened in the Balkans following the collapse of Communism and the break up of the former Yugoslavia.

Is it time to abandon the notion of Europe? We may wish to move away from a Eurocentric history, which assumes a homogeneous Europe with fixed boundaries and a single point of origin, but we cannot ignore the idea of Europe, which has been so vital not just in European history but in the histories of all the peoples who have come into contact with Europeans. The idea of Europe is still associated with universal values in the minds of many people, including Europe's enemies. Europe no longer endeavors by force to impose its version of civilization on the world, but European influences can be detected everywhere one looks. Together with the equally powerful symbolic concepts of Asia, Africa, and America, Europe as a signifier remains fundamental to any understanding of the world at large. World history cannot afford to be Eurocentric, but it runs an enormous risk if it neglects the ways in which the idea of Europe has, for better and for worse, shaped and been shaped over centuries of contacts with other world regions.

Europe, Eastern

Historians have difficulty defining Eastern Europe, questioning whether it should be considered a fundamental piece of Europe or part of the western frontier of Asia. Overlapping religions, economics, and cultural themes have led some to consider these countries “less European” than other European countries. Experts estimate that four more decades may be needed for Eastern Europe to catch up economically with its western neighbors.

Eastern Europe has been termed the heart of Europe and Europe’s suburb—both the crossroads of the continent and the borderland of Western civilization. The debate over Eastern Europe’s proper definition—an integral part of Europe or the western frontier of Asia?—illustrates the region’s historical place as a march land: an area where religions, empires, economic spheres, and cultural zones have overlapped and conflicted. Some view the term *Eastern Europe* as a relic of the Cold War division of Europe—hence its use as a formal capitalized term here, as opposed to *western Europe*, which is meant more as a geographic location. Other designations have also been proposed. *Central Europe*, which suggests the region’s vital contributions to Europe, is proposed for the region as a whole or in part (usually Poland, the Czech Republic, Slovakia, and Hungary). And because the term *Balkans* connotes backwardness and ethnic strife, *Southeastern Europe* is offered as a designation for the lands south of the Danube. In these terms, we see the disputed notions of the region: is it an integral part of democratic, capitalist Europe, or an area that is “less European”—culturally, economically, politically—than its western neighbors?

Defined as the nineteen post-Communist states between the Russian Federation and the German and Italian states (including six former Soviet republics and seven states of the former Yugoslavia), Eastern Europe is a region of 190 million people and over thirty ethnolinguistic groups. Diversity of languages, cultures, and religions is a primary characteristic of this region, one that has had both positive influence on the region’s history and, as shown in the wars of the 1990s in Yugoslavia, devastating consequences.

Geography and Population

Eastern Europe has no definite geographic boundaries. The North European Plain stretches from northern France across Poland, the Baltics, and Belarus, and into the Eurasian steppe. A spine of mountains—running from the Alps, through southern Germany and the Czech lands, to the Carpathians—separates the North European and Hungarian plains. South of the Danube, crisscrossing chains of mountains divide the region into remote valleys. Coastal areas are limited. The principal navigable rivers—the Oder, Vistula, Dnieper, Dniester, and Danube—flow to enclosed seas (the Baltic and the Black). South of the Danube, there are no major waterways, and the Adriatic coast is separated from the arid interior by the Dinaric Alps.

Riverine and maritime transportation have not been decisive factors in Eastern Europe’s history, compared to the western part of the continent; the overland movement of peoples, goods, and ideas has been the essential factor in the region’s development. As the trunk connecting the European promontories to Eurasia, Eastern Europe was the path of migration

for Germanic and Hunnic tribes in the fourth and fifth centuries CE; Bulgars and Slavs in the seventh and eighth; Magyars in the ninth; and Germans and Jews, migrating eastward, in the twelfth and thirteenth centuries. In the Middle Ages, major overland trade routes crossed Eastern Europe, connecting the German and Italian states with Constantinople and the Baltic Sea. And the region has been devastated by the epic conflicts of western Eurasia, from the ravaging of Attila in the fifth century to the Nazi–Soviet campaign in the twentieth.

The lands of Eastern Europe have offered a variety of natural resources. The plains of Poland, Hungary, and Ukraine are areas of abundant agricultural production, supplying grain for centuries to western Europe, Constantinople/Istanbul, and Moscow. During the medieval centuries, mining was an important activity throughout the region, with gold, silver, copper, tin, iron, and salt extracted from the mountains of the Czech lands, Slovakia, Transylvania, Bosnia, and Serbia. In the nineteenth and twentieth centuries, coalfields were mined in the Czech lands, Poland, and Ukraine, and oil and gas deposits were tapped in Romania and Ukraine.

Although some of these mineral and agricultural resources were processed and consumed within the region, for the most part Eastern Europe has produced raw materials for neighboring states. A principal reason for this disparity in consumption was the low population density in Eastern Europe. In the eleventh century, the estimated population density of Italy was 24 people per square kilometer, and in France, 16 people per square kilometer. In the Czech lands, in contrast, population density was only 7.8 people per square kilometer; in Poland, 5 people per square kilometer. By the late Middle Ages, when cities were emerging as economic and cultural centers in Western Europe, only a handful of cities in Eastern Europe had populations over 10,000: Prague, Wrocław/Breslau, Gdańsk/Danzig, Krakow, Kiev, and Smolensk. Contemporary capitals such as Ljubljana (Slovenia), Zagreb (Croatia), and Sofia (Bulgaria) had populations under 25,000 until the early twentieth century. At that time, population density across much

of Eastern Europe was still less than 100 people per square kilometer. In most areas south of the Danube, it was less than 50 people per square kilometer. Marked increases in population and urbanization did not occur until after 1950.

Other demographic indices further illustrate Eastern Europe's standing as a march land. The British demographer John Hajnal has drawn a line demarcating the "European Marriage Pattern" through Eastern Europe, from St. Petersburg to Trieste. To the west of that line, Hajnal and others have observed, medieval Europeans married later than people in most other world regions (the average age of first marriage was in the mid-twenties, while some 10 to 20 percent of people remained single) and established single-family households. To the east of that line, and in most areas of the world, marriage was nearly universal, couples married at a young age (late teens to early twenties), and multifamily households were organized along patrilinear lines. In the lands that Hajnal's line crosses (the Baltics, Poland, the Czech lands and Slovakia, Hungary, Slovenia, and Croatia), patterns of medieval marriage and household composition followed both western and eastern models.

This same line also serves as a boundary in mapping indices of economic and social modernization: in the mid- to late 1800s, levels of gross domestic product (GDP), industrial output, and density of rail lines were far higher to the west of the line; by the 1930s, there was also a large disparity in literacy rates and infant mortality. As with Hajnal's mapping of the European Marriage Pattern, areas of Poland, Slovakia, Hungary, Slovenia, and Croatia were a transitional zone. In terms of demographic and economic measures, the Czech lands in the 1930s were most like western Europe: the literacy rate was 96 percent, and over half the population lived in urban areas and was engaged in industrial or commercial activity. Furthest removed from western European indices were Bulgaria, Albania, and the southern regions of Yugoslavia. In Albania, in the 1930s, only 12 percent of the population lived in urban areas, and the literacy rate was only 30 percent. In her studies of Albania and Montenegro from the early 1900s, the anthropologist

A statue commemorates Communism in Poland, 1985. Many such memorials, once common in Communist Eastern Europe, were torn down after the collapse of the Soviet Union in 1991.

M. E. Durham observed patriarchal tribal societies, a justice system based on blood vengeance, and cultural practices that blended Islam and Catholicism with belief in vampires and the evil eye.

Economic Development

Eastern Europe offers a classic example of a peripheral economic zone, a region that is dependent upon more populous and developed areas—in this case, for the export of raw materials and the import of capital and technology. Eastern Europe has been in a peripheral relationship not only to the western European core, but also to Constantinople/Istanbul and Moscow. At various times, these imperial powers competed with each other or with western European states for control of the region's resources. In the fifteenth and sixteenth centuries, the Ottoman Turks vied with Venice for silver and other resources in Bosnia and Serbia, leading to a series of wars. The Ottomans were forced to surrender the agricultural areas of Ukraine and the Danube delta in wars with Russia in the 1700s. And imperial and Soviet Russia sought to offset Austrian and German influence in southeastern Europe and Poland in the nineteenth and twentieth centuries.

A consequence of these overlapping economic interests is that, from the later medieval period through the twentieth century, Eastern Europe's natural resources have been extracted largely for the benefit of its neighbors to the west, east, and south. After

the Ottoman conquest of Constantinople in 1453, foodstuffs from Ukraine and metals from Bosnia and Serbia fueled the capital's rebuilding. North of the Danube, the Austrian Habsburgs and their German bankers gained control of the mineral resources of the Czech lands and Slovakia in the sixteenth and seventeenth centuries. The word *dollar* is derived from *Joachimsthaler*, a silver coin minted in present-day Jachymov, Czech Republic, that the Habsburgs circulated in the seventeenth century. This export of natural resources did generate some prosperity in the region. But, for the most part, because of its dependence upon or exploitation by neighboring states, the economic development of Eastern Europe was stunted. In the late medieval period, landowning nobles in Poland and Hungary seized upon high profits to be gained in the export of grain and cattle to German and Italian markets. This export of foodstuffs resulted in the gradual transformation of the agrarian system from a tenant economy, in which peasants paid rent to the lords, to a feudal structure that restricted peasant mobility and obliged them to work the lords' estates. Thus, at the same time parts of western Europe transitioned from a feudal to a market-based economy, Eastern Europe experienced a "second serfdom." Economic power remained in the hands of the landed nobility, who invested their profits in manors and luxury goods.

Banking, industry, and commerce were limited in the late medieval and early modern periods. Jews,

Armenians, and Germans scattered in the region controlled most commercial and industrial activities. During the fourteenth and fifteenth centuries, caravans along the trade route between Akkerman on the Black Sea and L'viv/Lwów (Ukraine) were always under the direction of Armenian merchants. Merchants in L'viv—whether Armenian, Jewish, German, Tatar, Polish, or Italian—traded wheat, fish, caviar, and cattle for pepper, cotton, and silk. Slaves were also important commodities: between 1500 and 1650, some ten thousand slaves—seized in Poland, Ukraine, and southern Russia—were exported each year to Istanbul.

Lacking a prominent middle class and domestic markets, Eastern Europe's economy was slow to industrialize. By the late 1800s, isolated areas of industrialization had emerged: the Czech lands were an important manufacturing area in the Habsburg Empire; the region around Lodz, Poland, produced 40 percent of the Russian Empire's coal and nearly a quarter of its steel; and Budapest was one of the world's largest centers for milling flour. For the most part, however, industrialization was limited. In the 1930s, over 75 percent of GDP in Albania, Bulgaria, Lithuania, Romania, and Yugoslavia was agriculture; after Czechoslovakia, the largest industrial sector was in Hungary, where industry was only 24 percent of

GDP. Development of industry, transportation, and communications in the late nineteenth and early twentieth centuries was generated largely through foreign investment. Austrian, German, and French firms owned factories, railroads, and shipping lines in the region. Foreign companies owned 95 percent of Romanian oil deposits. The other driving force behind the region's economies was state interference in or direction of development. Thus, the economic central planning of the post-World War II Communist regimes was not a great departure from the pattern of preceding decades. Under the Communist regimes, the Eastern European economies were tied to each other and to the Soviet Union in the COMECON trading bloc. Industrialization advanced rapidly in the region, although at a steep cost: resources and finished goods were exported, below market value, to the Soviet Union, while factories scarred the landscape of the region, particularly the northern Czech lands, southern Poland, and Romania.

Frontiers between Religions

The indistinct boundaries of the Catholic patriarchates of Rome and Constantinople also met in Eastern Europe, and missionaries from both cities brought Christianity into the region. Both the Roman pope

and the patriarch in Constantinople recognized the early mission of the brothers Cyril (c. 827–869) and Methodius (d. 885). Sent from Constantinople, Cyril and Methodius carried the Christian faith north of the Danube, together with a Slavic literary script to be used for liturgy. Even in areas that were loyal to Rome after the Great Schism of 1054, this liturgy and script, known as Glagolitic, continued to be used: in Poland and the Czech lands, the Slavic rite persisted until the twelfth century; in Croatia and Dalmatia, Glagolitic was the script for liturgical texts into the twentieth century. This script became the basis for the Cyrillic alphabet used today in Russia, Ukraine, Serbia, Bulgaria, and other nations.

Following the mission of Cyril and Methodius, competition arose between the Latin church, with its German allies, and the Greek church, which was backed by Byzantine power. Local princes looked both to Rome and Constantinople. Duke Borivoj (d. 889), founder of Prague, was baptized into the Slavic rite, while the Bulgarian czar, Boris I (d. 889), exchanged letters on theological questions with the Roman pope. Their choices, and the success of one rite or the other in a particular principality, resulted more from political exigencies than religious conviction. The expansion of the Roman church in the Czech lands and Poland during the ninth and tenth centuries was due largely to German bishops and the emperors Otto I and Otto III. In 917, the patriarch in Constantinople established an independent patriarchate for the Bulgarian church. Although independent, this new church followed the Slavic rite and maintained loyalty to Constantinople—thus remaining free from Rome. This competition between the ecclesiastical authorities, and local princes' strategies of playing Rome off against Constantinople, continued after the Great Schism of 1054 separated the patriarchates into the Roman Catholic and Orthodox churches. In the fourteenth and fifteenth centuries, the two churches vied for converts in the last pagan areas of Europe: an arc from Lithuania through Belarus and Ukraine to the Black Sea. At the same time, in mountainous Bosnia, a church emerged that was independent of the two authorities and combined elements of both

Latin and Slavic-Greek traditions. By the mid-1400s, though, this Bosnian church was broken, largely through the efforts of Franciscan missionaries, and both Catholic and Orthodox churches competed for its former adherents.

The religious map of Eastern Europe was further colored by migrations, invasions, and reform movements of the late medieval and early modern periods. Ashkenazic Jews, speakers of Yiddish, migrated from the Holy Roman Empire into Poland in the twelfth through the fourteenth centuries, and into Lithuania, Ukraine, and Romania in the fifteenth through seventeenth centuries. Of the 7.5 million Jews living in Eastern Europe in 1900, 70 percent lived in these areas. The Sephardic Jews of southeastern Europe, distinct from the Ashkenazim in custom and language, were descendents of the Jews expelled from Spain in 1492 and welcomed into the Ottoman Empire. The Sephardim numbered 193,000 in 1900, most in cities such as Sarajevo and Salonika. The Ottoman expansion into southeastern Europe in the fourteenth and fifteenth centuries also brought Islam into the region. According to the Ottoman census of 1520–1530, Muslims were 18.8 percent of the population in the empire's European lands. Muslims also congregated in towns: the population of Sofia, for instance, was over 66 percent Muslim, while the surrounding district was only 6 percent Muslim. These Muslims included Turkish officials, soldiers, and artisans, as well as converted Greeks, Albanians, and Slavs. Conversions were due largely to Islam's adaptability to local folk religion, rather than firm conviction, and many Muslims of southeastern Europe maintained ties to Christianity. In some rural areas, peasants went to the mosque on Friday and church on Sunday.

The Reformation and the Counter-Reformation further stirred the region's religious waters. Martin Luther acknowledged the influence of early reformer Jan Hus (c. 1372–1415), a Czech priest and critic of Catholic doctrine. Although the church executed Hus as a heretic, Catholic armies failed to suppress his followers in the Czech lands. With the ground prepared by the Hussite challenge, branches of the Protestant

Reformation found adherents in the Czech lands, as well as in other areas of Eastern Europe, in the early 1500s. Lutheranism advanced into the Czech lands, Slovenia, and Poland in the 1520s. The Reformed (Calvinist) movement spread rapidly in Hungary and the Ottoman vassal state of Transylvania. Calvinism also gained adherents in Poland and Lithuania, where Reformed universities were founded in the 1620s. Anabaptist and Anti-Trinitarian (Unitarian) sects also took root in Poland, Lithuania, and Transylvania. In Transylvania, Prince István Báthory (reigned 1571–1586) recognized the Unitarian, Catholic, Lutheran, and Reformed faiths as accepted religions of the state. This toleration was unusual in Eastern Europe—and in Europe as a whole. By the late 1500s and 1600s, in the Czech lands, Poland, Hungary, and Slovenia, Jesuits and Catholic nobles succeeded in reestablishing Catholic dominance and outlawing Protestantism throughout much of Eastern Europe.

Political History

During the medieval period, independent kingdoms in Eastern Europe rivaled states to the west and east. Under Czar Simeon (reigned 893–927), Bulgaria dominated the lands south of the Danube, from the Black Sea to the Adriatic. During the reign of Charles IV as Holy Roman Emperor (reigned 1346–1378), Prague became the leading city of the region, and the site of the first university north of the Alps. And the Hungarian court at Buda, under Matthias Corvinus (reigned 1441–1490), was a center of art and learning in the early Renaissance. In the early modern period, however, the independent states of Eastern Europe ceased to exist, as the region came under the political control of rival empires. The threat of Protestantism in the Czech lands and the Ottoman Turks in Hungary led to the consolidation in the early seventeenth century of an empire ruled by the Catholic Habsburgs. In 1683 the Ottoman Turks' final advance into Europe was halted at the Habsburgs' seat, Vienna, and, less than two decades later, the Habsburgs had seized Hungary and Transylvania

from the Ottomans. At the same time, new expansionist powers were emerging in the east (Russia) and the northwest (Prussia). In the early 1700s, under Peter the Great (Peter I, reigned 1682–1725), Russia pressed south into Ukraine; and at the end of the century, under Catherine the Great (Catherine II, reigned 1762–1796), the empire partitioned the territory of the weakened Polish kingdom among Habsburg Austria, Prussia, and itself. Following the Napoleonic wars, these imperial powers—Austria, Prussia, Russia, and the Ottoman Empire—claimed all the lands of Eastern Europe.

Yet, at the same time as the neighboring powers culminated their advance into Eastern Europe, local movements began to challenge imperial power. Over the course of the nineteenth century, these initiatives developed into mass nationalist movements. Motivated by ideas imported from western Europe—the French idea of the nation as a source of sovereignty and the German conception of the nation as a community united by language and culture—regional elites assembled the components of national communities: codified languages, books and periodicals in those languages, national histories, and institutions for education and culture. From the mid-nineteenth century, national movements demanded linguistic and educational rights and administrative autonomy. Violent confrontations with imperial authorities erupted in several areas: Poland (1830, 1846, 1863), Hungary (1848), Bosnia (1875), Bulgaria (1876), and Macedonia (1903). While the Russians suppressed Poland and the Austrian Habsburgs granted autonomy to Hungary, the emerging national movements of southeastern Europe embroiled the region into the early twentieth century. Ottoman weakness and the scheming of the independent states of Greece (independent in 1830), Serbia (1878), Romania (1878), and Bulgaria (1878) stoked the incendiary situation in the region. Bloody wars in 1877–1878 and 1912–1913 and other economic and diplomatic crises drew the major European powers—Austria-Hungary, Britain, and Germany—into a complicated tangle in the region. A Serbian student's assassination of the Habsburg heir, Archduke Franz Ferdinand, on 28 June

1914, precipitated the unraveling of that tangle and led to the start of World War I.

World War I brought the creation of new independent states in Eastern Europe (Estonia, Latvia, Lithuania, Poland, Czechoslovakia, and Yugoslavia), but the process of building ethnically homogenous polities out of the former empires continued throughout the twentieth century. “Ethnic cleansing,” a term that entered the universal lexicon during the wars of the former Yugoslavia (1991–1999), has been a stain on the region’s history since the wars of 1877–1878 and 1912–1913, when Slav, Romanian, and Greek armies expelled thousands of Muslims. The expansion of Nazi German military power into the region, followed by the Soviet Union’s devastating victory, accelerated the segregation of national groups. In addition to the 4.5 to 5.4 million Jews of the region who perished at the hands of the Nazis and their local accomplices, another 9 to 10 million people—mostly Poles, Belarusians, and Ukrainians—were killed during the German advance of 1939–1941. The Soviet regime deported some 1.5 million Poles and Ukrainians to Asia, while 5.5 million people from throughout the region were forced into labor in Germany. Following the war, over 18 million people were resettled, including over 8 million Germans expelled from Poland, Czechoslovakia, and Hungary.

After the collapse of the Communist regimes in 1989 and 1991, the efforts at creating nation-states continued, with the establishment of independent post-Soviet republics (the Baltics, Belarus, Ukraine, Moldova) and the peaceful split of Czechoslovakia in 1993. The conflicts in the former Yugoslavia (1991–1999) showed that nationalist identities, when mixed with economic decline and political provocation, remain a deadly force in the region.

The Twenty-First Century

Over two decades after the collapse of the Soviet bloc in Eastern Europe, the region is again a march land of economic, political, and cultural spheres. In 2004 and 2007, ten former communist states join

the European Union. Yet the former Yugoslav states of Bosnia, Macedonia, and Kosovo remain unstable after the wars of the 1990s, and the former Soviet republics of Moldova, Ukraine, and Belarus are beset by economic and political problems. Eastern Europe remains an exporter of natural resources. The principal resource now is labor: industrial workers find jobs throughout western Europe, while educated young people leave for universities—and jobs—in western Europe and North America. Meanwhile, the financial crisis that began in late 2007 revealed how incomplete and fragile were the economic changes of the immediate postcommunist period. The road of economic and political transformation is long. According to estimates, even the region’s most advanced countries (Poland, Hungary, Czech Republic) will not reach western European economic levels for another three to four decades.

European Expansion

Contrary to many popular conceptions, the expansion of European culture actually predates the voyages of Columbus by more than a millennium. From the Greeks, Romans, and Vikings to the nineteenth century, European expansion has typically pursued certain goals: economic prosperity, increased trade, new lands for settlement, and religious converts.

The dominant force in shaping our global society has been the expansion of European society and culture throughout the world following the voyages of Columbus. Some have seen the explosive movement of Europeans throughout the world as a consequence of centuries of repression and cultural darkness that had kept Europeans from exploring the world beyond Europe. One of the most striking examples of that perspective is Washington Irving's biography of Columbus, in which Irving identified the expansion of Europe as one of the fundamental elements of modernity and Columbus as the first modern man, the one who cast off the blinders that had limited European development.

The Ancient World

The expansion of Europe and of European culture has a history that long precedes Columbus's first voyage. The post-1492 expansion of Europe built upon the expansion of the previous five centuries and reflects a characteristic of ancient European culture as well. The ancient Greek city-states expanded, establishing colonies in Sicily and southern Italy, to which they brought Greek cultural values and practices. The conquests of Alexander of Macedon (Alexander the

Great, 356–323 BCE) spread Greek cultural values throughout much of the Middle East and then into the Roman world. According to his biographer, Arrian, Alexander came to see his conquests as the beginning of a world-city, a worldwide community within which all mankind would live in harmony under the guidance of the Greeks.

The Roman Empire also generated a wide cultural community as it expanded from its home in central Italy. Its influence extended well beyond the formal boundaries of the empire, as the barbarian societies along the frontiers adopted elements of Roman culture in the course of their contact with Roman soldiers and merchants.

Greek and Roman expansion was not worldwide, however. The Asian goods that the Romans desired traveled to Rome via ancient trade routes, so that there was no need to seek direct access to the Asian markets. Although Alexander of Macedon was said to have believed in some kind of world community, this was not a concept of much significance in the ancient world. Stoic philosophers did have some sense of a universal human community, but this was the view of a small elite and had little practical consequence.

Medieval Christendom Expands

The beginning of the great era of European overseas expansion associated with Columbus is sometimes linked to the desire to have direct access to the markets of the East, and the creation of a world system beginning in the sixteenth century is often discussed in primarily economic terms, a world economic system. But the desire to preach the Christian Gospel to all mankind was another spur to expansion. The

Christian missionaries from Europe accompanied merchants and adventurers around the world but often went off to explore on their own. Shown here is a section of the map David Livingstone used during his travels in Africa.

Christian conception of mankind as a single family descended from Adam and Eve and redeemed by Christ motivated missionaries to spread beyond Europe and into regions inhabited by infidels. Christians, echoing the Stoics, could conceive of a universal community embracing all mankind, but they envisioned an institutional structure provided by the Church.

The role of Christianity in the expansion of Europe stretches back to the Byzantine imperial government's support of missionary efforts to convert the Goths in the third century CE. From the imperial point of view, such an effort was in keeping with the older tradition of acculturating barbarians to the Roman way of life. The expansion of Christianity could thus go hand in hand with the expansion of the Byzantine Empire, a kind of relationship that was to have a long history.

The Latin church in the West was slower in getting involved in expansion beyond the boundaries of the Roman Empire. Initially it was individuals who went forth to preach the Gospel in the lands of the barbarians. Saint Patrick (fifth century), for example, went

to preach to the Irish, a people who had never been subject to the Romans.

The first pope to authorize a mission to a non-Christian society was Gregory I (c. 540–604) who sent a team of missionaries to England, where Christianity had virtually died out after having been introduced during the Roman occupation of the island. The missionaries were followed by other figures who brought England into regular contact with the continental world. During the eighth and ninth centuries, missionaries from Ireland and from England in turn went to the borders of the Carolingian Empire with the support of various Carolingian rulers and with papal blessing to preach to the Germanic peoples, bringing them into the church and under Carolingian domination. This union of spiritual and temporal goals was to be a characteristic of subsequent European expansion.

The Internal Colonization of Europe

With the weakening of Roman power and the population decline that accompanied it, only churchmen

Columbus's three ships: the *Nina*, the *Pinta*, and the larger *Santa Maria*. F. E. Wright, New York Public Library.

were at all concerned with expansion until about the middle of the tenth century. The end of the long series of barbarian assaults on the Roman and Carolingian societies and the beginning of a period of warmer climate from about 950 to 1300 contributed to population growth that reignited pressures to expand. This period began with what the historian Archibald Lewis described as the colonization of the internal frontier of Europe. Forests were cut down and new farming villages and trading towns established. Many of the techniques later used to organize migration to new frontiers on the edge of Christendom and to establish new communities overseas were first developed in the course of this process of internal European colonization.

From the tenth to the fourteenth century Europeans moved aggressively in all directions with varying degrees of success. To the east, the twelfth- and thirteenth-century crusades to regain the Holy Land ultimately failed, but German expansion eastward into the lands of the Slavs that had begun in the early tenth centuries was successful. In the north, during the tenth and eleventh centuries Christian missionaries succeeded in converting the Scandinavians, bringing them into the European Christian cultural orbit, eventually leading to the settlement of Greenland from the eleventh century and the establishment of Christian churches there. Around 1000, Scandinavian adventurers even reached the mainland of North America. To the west and south, the Portuguese and the Spanish were pushing the Muslims back, and further to the west, the English were advancing into the Celtic lands that bordered England, reforming

the Celtic branch of Christendom and bringing those churches into conformity with Roman practice.

Medieval thinkers developed legal justifications for expansion and conquest that supplemented the military and missionary justifications; these were later used during the Spanish conquest of the Americas in the sixteenth and seventeenth centuries. First developed in the course of Christian encounters with the Muslims and the Mongols during the thirteenth century, these legal justifications forced those who supported the crusades and other forms of armed force against nonbelievers in the process of expansion to justify their actions in legal terms.

During the fourteenth and fifteenth centuries, as the climate turned colder and the Black Death reduced the European population by at least one-third, and as the Ottoman Turks moved further up into the Balkans, dominating more of the Mediterranean, the era of medieval expansion slowed but did not entirely stop. At the western edge of Europe, the Portuguese continued to have a strong interest in expansion as they sought to find a sea route to the markets of Asia that would circumvent the traditional Muslim-controlled routes through the Near East. This required establishing settlements to refit and resupply ships that would make the long journey to the East. The Portuguese were also anxious to protect themselves from Muslim counterattacks and were interested in reconnecting with Christian communities of Asia that, it was thought, might join in a last great crusade. Finally, the Portuguese were interested in converting the non-Christians of the East to Christianity.

Europeans Expand Overseas

All of these motives for a renewal of European expansion, this time well beyond the geographical boundaries of Europe, appear in the literature of the fifteenth century. Portuguese expansion into the Atlantic and along the west coast of Africa, popularly associated with Henry the Navigator (1394–1460), led to the rediscovery of the island chains of the Atlantic, Canary (1340–1341), Madeira (1418–1419), Azores (1427–1431), and Cape Verde (1455–1457), and to

the establishment of trading posts on the coast of Africa. Portuguese interest in finding a water route to Asia was encouraged by Genoese financiers, merchants, and seamen who had suffered financially when the Muslims had conquered the Genoese settlements along the Black Sea.

The Age of Columbus

It is, then, no coincidence that it was an ambitious Genoese sailor who had lived and worked in Portugal who initiated the great age of European expansion that eventually led to the development of an international society, if not a true world community. In addition to the motives for expansion mentioned earlier—a desire to find new routes to Asian markets, to preach the Gospel to nonbelievers, and to find Eastern Christian communities to join in a last crusade, Columbus sought personal social and economic advancement. He bridged the two periods of European expansion, employing the motives and experience of medieval expansion in the course of his encounter with the New World.

Columbus's great significance is that he began the process that opened up not only water routes to the already known Asian world but also to entirely new worlds, the Americas and the Pacific Ocean in particular, as well. The novelty of these new worlds was not, however, initially appreciated. Until his death Columbus claimed to have reached the outer edge of Asia, a belief rooted in the medieval theory that the surface of the Earth was almost entirely land and that the Ocean Sea was a narrow band of water, rather like a river, separating the various landmasses. That being the case, the islands of the Caribbean would have to be the outer edge of Asia. Likewise, Columbus initially identified several plants found in the Americas with the spices associated with Asia, although later he changed his mind. From 1492 to about 1600, Europeans tended to perceive the New World in terms derived from the experience of the Middle Ages, approaching the peoples of the Americas as if they were at a stage of development similar to that of the barbarians who had invaded the Roman Empire.

The European discovery of the Pacific Ocean by Vasco Nuñez de Balboa in 1513 and then the circumnavigation

of the Earth by Magellan's fleet (1519–1522) stimulated the reexamination of European theories about the surface of the Earth and the peoples who lived there. One result was the realization that the Ocean Sea was not an obstacle to direct access to Asia but a highway that would enable Europeans to sail to all parts of the Earth, a viable alternative to traveling overland. A second result was a growing realization that there existed a wide variety of peoples and societies throughout the world, ranging from the most primitive to the most sophisticated. This experience challenged traditional biblically based theories about mankind, eventually leading to the development of anthropology.

A European World Order

The long-term consequences of the European encounter with the rest of the world can be illustrated graphically in several ways. By 1763 European powers were rising stars among the great imperial powers that politically dominated, at least nominally, the bulk of the globe. Seen in economic terms, the European encounter with the rest of the world generates a map showing the major trade routes that, when taken together, outline what the sociologist Immanuel Wallerstein has labeled the modern world system, a series of cores and peripheries linking all parts of the world in a single economic order.

Less easy to illustrate graphically is the interpenetration of cultures that was also occurring. In physical terms, this included the importation of a wide variety of products into Europe from elsewhere, products ranging from the traditional Asian spices and silks to such new items as tobacco and potatoes from the Americas. This latter was part of what the historian Alfred Crosby termed the Columbian exchange—the massive movement of flora and fauna (including agents of disease) in both directions across the Atlantic after the European discovery of the Americas.

Above all, the importation of a large amount of precious metal, especially silver, from the Americas had a significant impact on the European economy. Perhaps even more interesting was the fact that so much of that specie passed through European hands and on to Asia. Some recent scholarship has suggested that

in fact the drain of silver to the East has been one of the major forces shaping the world economy.

Consequences of European Expansion

The desire of Europeans to acquire goods from elsewhere sometimes meant the restructuring of other economies to meet those needs. The demand for sugar that had originally led to the creation of sugar plantations on the islands of the Mediterranean in the Middle Ages led to the creation of similar plantations on the Cape Verde Islands and then on the islands of the Caribbean. This development generated a demand for labor, a demand that the European population could not (or would not) meet, thus generating a market for slaves. Eventually, Europeans turned to Africa as the source for such labor, redirecting the long-standing African slave trade to the New World and away from its traditional markets in the Muslim world.

There were other consequences of European expansion, as Christian missionaries accompanied merchants and adventurers around the world, preaching the Gospel to new ears. The impact of these efforts varied widely, from the mass baptisms that Catholic missionaries often employed in the initial stages of conversion efforts in Latin America to the tiny number of converts that the Jesuits made over several decades of sophisticated missionary efforts at the highest levels of Chinese society. Another result was the development of cults that blended Christian and local beliefs and practices, as well as the incorporation of local beliefs into the Christian context. There also emerged new populations, mestizos and creoles, who reflected the movement of peoples, voluntarily and involuntarily, around the world. Such peoples reflected not only new mixtures of physical characteristics but new languages and dialects as well.

The final consequence of European expansion was the gradual development of a conception of mankind as a community. This is reflected quite clearly in the development of a body of international law designed to regulate relations among the states of the world. This legal order was linked to a conception of mankind rooted in an anthropology that saw a progression from primitive hunter-gathers through

pastoralists to agriculturists and from life in the fields to life in urban communities. On the basis of this anthropology, the powerful imperial states were able to assert their superiority, culturally as well as militarily, to all the other human societies and to restrict leadership of the worldwide legal order to the Christian nations of Europe. They could also justify their conquest and domination of large parts of the world on the grounds that they were assisting the development of peoples still at the lower stages to reach their full human potential, an attitude that evolved into racism.

The Decline of Empires

The overseas expansion of Europe that began in 1492 was not an abrupt change in the course of European history. It was an integral part of a process that had developed between 1000 and 1300. In that period, many of the intellectual and institutional structures associated with post-1492 expansion were first created, structures upon which the explorers, missionaries, and settlers who followed Columbus built. The ironic consequence of the success of European expansion was that by the late eighteenth century, the oldest European colonial possessions in the New World were on the verge of a series of revolutions that were to overthrow European political domination without separating the new states from the European economic and cultural world. This in turn was the first stage in a process that only ended in the late twentieth century in a wave of decolonization that destroyed the great European empires. In their place, to an extent not always appreciated, the modern conception of an international order with a legal and institutional structure as an armature has implemented the Stoic and Christian conception of an international community. The empires faded away, but the cultural legacy remained.

European Union

The European Union (EU) is an economic and political union of twenty-seven European member-states (as of 2010). The EU is the most integrated of any regional bloc, operating as a single market with a common currency. It also maintains a range of common policies, including trade and agriculture, and increasingly shared foreign and defense policies. EU citizens enjoy free movement and exchange across member countries.

After World War II destroyed the economies and financial markets of Europe, nations were determined to rebuild their shattered economies, recover their influence, and—above all—ensure that such a catastrophe would never happen again. The restoration process was stimulated by the U.S.-led Marshall Plan, which provided European countries with financial allowances. Primarily, the new continent had to prevent antagonism between Germany and France. Many people supported the idea of a politically unified Europe and proposed a European federation or some form of European government. On 19 September 1946, the English statesman Winston Churchill gave a speech at the University of Zurich outlining his vision of a “United States of Europe” similar to the United States of America. The idea prevailed, and the Council of Europe was created in 1949, even though it remains a restricted organization today. The Council of Europe did not hold any legislative power or a right to vote. It was, and still is, a forum of political exchange to defend human rights, parliamentary democracy, and the rule of law.

Three Communities

The European Union of today grew out of three separate communities: the European Coal and Steel Community (ECSC), the European Economic Community (EEC), and the European Atomic Energy Community (EAEC). Each of these communities had its own commission as well as its own council. All three communities had the same members continuously.

Early in 1951 France, Germany, Belgium, Luxembourg, the Netherlands, and Italy founded the ECSC, an administrative agency overseeing the production of coal and steel. On 9 May 1950, the French foreign minister, Robert Schuman, publicly presented his plan of pooling the coal and steel resources of the member states to create a unified market for their coal and steel products. This plan became famous as the “Schuman Declaration,” which was drafted by the French civil servant Jean Monnet. Initially the United Kingdom was invited to join the community as well but refused for sovereignty reasons.

By 1954 the ECSC managed to lift restrictions on imports and exports, creating a unified labor market as well as a common set of rules; between 1952 and 1960 steel production rose by about 75 percent. At that time coal and steel were the primary resources for industrialization. The Treaty of Paris of 1952 formally established the ECSC. A few years later the ECSC member states attempted to further integrate politically and militarily. They intended to create the European Political Community and the European Defence Community (EDC), having in mind a European military service under joint control as well as a federation of European states. Regardless of the treaty

A sign announcing the price of clothing in euros hangs in a market in Athens, Greece, in 2003. Adopting the euro as the currency of the European Union has proved a contentious issue among member nations.

that was reached between the member states, the French National Assembly failed to ratify the treaty, and thus the EDC was buried. In 1955 the Western European Union settled in its place.

Soon after ratification failed, the member states of the ECSC reiterated their desire for further integration and founded the European Economic Community along with the European Atomic Energy Community. The EEC was established by the Treaty of Rome in 1957 and formed a customs union among the six founding countries in 1958. Experts thought that deeper economic integration would lead to a political union. The EEC worked for the liberalization of the flow of goods, services, capital, and people; the abolition of trusts and cartels; and the development of joint and reciprocal policies on labor, social welfare, agriculture, transport, and foreign trade. The EEC was the most important of the three communities.

The EAEC—also known as Euratom—arose as the third treaty organization and was also established by the Treaty of Rome in 1958. Euratom's aim was the collaboration of member states in peaceful nuclear research to ensure the free movement of nuclear raw materials, equipment, investment capital, and specialists within the community, and to promote European nuclear research rather than transnational competition. Euratom's authority was limited to civilian use of atomic energy.

Because the United Kingdom did not participate in any of the three communities, it proposed that the Common Market to be expanded to North America. London initiated European Free Trade Association (EFTA) negotiations, which were finalized in 1960 and joined by the European countries that were not members of any of the other three communities. During the 1970s EFTA and EEC negotiated various free trade agreements to reduce trade barriers and in 1979

introduced the European Monetary System (EMS), which helped to stabilize the currencies after two major oil crises in 1973 and 1979.

The European Community

With the Treaty of Brussels in 1965, Euratom, EEC, and ECSC merged as the European Community. The treaty also joined the three commissions and councils as the single Commission of the European Communities and the single Council of Ministers of the European Communities. The French president, Charles de Gaulle, vetoed Britain's membership, which Britain had applied for in 1963 for the first time. Only after de Gaulle left office could Britain join the EC in 1973. At the same time Ireland and Denmark joined the EC. The Single European Act of 1987 created a single internal European market and abolished all trade barriers that might hinder the free flow of goods, services, and people. The community also further integrated political and social affairs. Almost ten years later Greece joined the EC in 1981, and Spain and Portugal joined in 1986. When Germany reunited in 1990 the former East Germany was automatically absorbed into the community.

The European Union

In 1993 the European Community changed its name to the European Union (EU). The name change was established by the Treaty of the European Union, which was signed in Maastricht, the Netherlands, in 1992 and ratified by the EU member states in 1993. Its articles laid the foundation for the single European currency, the euro (the proposal of a common European currency was taken seriously as early as the mid-nineteenth century), a central banking system, a legal definition of the EU, and a further integration in policy areas such as foreign and security policy. The treaty replaced the Treaty of Rome of 1957. The European Union absorbed the functions of the Western European Union in 1999, which automatically gave the EU military capabilities. In 1995 the EU invited

Austria, Finland, and Sweden to join, bringing the number of member states to fifteen.

On 1 January 2002 the euro replaced the old national banknotes and coins. One year later, in 2003, the Commission of the European Communities started negotiations with Estonia, Latvia, Lithuania, Poland, the Czech Republic, Slovakia, Hungary, Slovenia, Cyprus, and Malta for European Union membership. This latest enlargement became effective on 1 May 2004. Bulgaria and Romania joined the EU on 1 January 2007. Croatia, the former Yugoslav Republic of Macedonia, and Turkey are candidates to join the EU, while Albania, Bosnia and Herzegovina, Montenegro, Serbia, and Iceland are recognized as potential membership candidates. Kosovo is also seen as a potential candidate, but not all member states recognize its independence from Serbia.

In December 2007 European leaders signed the Lisbon Treaty, which was intended to replace the unpopular and failed European Constitution. When Irish voters rejected the treaty in June 2008, its immediate future also became uncertain. At a second poll on 2 October 2009, Irish voters endorsed the treaty. When the Czech Republic approved the Lisbon Treaty on 3 November 2009, it had been ratified by all member countries. It came into effect on 1 December 2009.

Headquartered in Brussels, Luxembourg, and Strassbourg, the key institutions of the EU include the European Parliament, the Council of the European Union, the European Commission, the European Court of Justice, the Court of Auditors, and the European Central Bank. In the early twenty-first century the European Union comprises around 500 million citizens and generates approximately 30 percent of global GDP. The European Union motto is *United in Diversity*, and is perhaps best represented by the fact that it has twenty-three official languages.

Expeditions, Scientific

Scientific expeditions are voyages of discovery that are essentially motivated by advancing knowledge and understanding of the unknown through various scientific techniques. These kinds of expeditions have been undertaken for millennia and include explorations and examinations of a wide range of scientific fields and disciplines, such as botany, astronomy, biology, geology, entomology, and oceanography.

Scientific expeditions are attempts to go beyond the traditional limits of geography, culture, and survival in order to further human knowledge by answering specific questions through observation in a disciplined scientific framework. Scientific expeditions are often motivated by a desire for adventure or national glory, yet they can also bridge or even erase cultural divides in the search of knowledge. In antiquity the Greeks undertook the first recorded observational voyages, and in the Middle Ages Chinese civilization mounted large sailing fleets for exploration. In the seventeenth century European scientific societies sponsored expeditions focused on solving specific problems. In the eighteenth century, European Enlightenment thinkers promoted both science and educational travel for the advancement of Western civilization, resulting in the great European circumnavigations and American continental expeditions. As scientific disciplines and training became narrower and more differentiated, expeditions focused on specialized studies to push distinct disciplinary boundaries. In the late twentieth and early twenty-first centuries, expeditions have focused on the last frontiers of scientific exploration, including remote regions like the Arctic and the Himalayas, the deep sea, and outer space.

Observations in Transit: Antiquity–1500

The earliest records of human civilization show a clear interest in both science and travel, but it is not until classical antiquity that we have evidence of the two coming together. Alexander of Macedon (Alexander the Great, 356–323 BCE) included philosophers and observers on his campaign throughout Asia and the Mediterranean (334–323 BCE) and established Greek scholarly and scientific traditions in many of the lands he conquered, thus adding a scientific component to an expedition of military conquest. The Greek Pythias traveled from Marseille to England around 300 BCE to purchase tin but also made a thorough scientific study of the journey, recording observations while on land and at sea. Pythias was the first to systematically measure latitudes while at sea, and, going beyond mere observations, he hypothesized a correlation between the tides and the phases of the moon.

Many voyages of the Middle Ages and the Renaissance counted botanists and other scientific observers among their passengers. None was close in scale or ambition to the vast expedition of the Chinese explorer Zheng He. His first voyage left Liujia harbor in July 1405 with some sixty-seven enormous ships and around 28,000 men, the largest scientific expedition ever undertaken. Sent by the emperor of the prosperous Ming dynasty (1368–1644), Zheng He's fleet was prepared to take measurements and record nautical information, including compass readings and other observations, in a regular logbook, a practice that appeared only later among European expeditions. The fleet crossed the South China Sea, visiting Java, Sri Lanka, and India, and returned in 1407.

The map on the right, an enlargement of the shaded rectangle above, shows the routes taken by Roald Amundsen, Robert F. Scott, and Ernest Shackleton in their race to reach the South Pole.

On subsequent voyages with fleets as large as two to three hundred ships, Zheng He traveled to Yemen, Mecca, Somalia, East Africa, and India. Zheng He was ordered to study carefully the customs of local peoples everywhere he went, and each voyage included a team of doctors, naturalists, and observers.

Problem-Solving Expeditions: 1500–1750

As the Ming dynasty lost its wealth and prominence on the world stage (seafaring expeditions were even forbidden by order of the emperor in the late fifteenth century), European developments in sailing and science accelerated rapidly. As European monarchs began to spread their power and influence beyond the Mediterranean world to Africa, South Asia, and the Americas, these became new arenas for scientific expeditions. At the same time, European science was becoming a professional and often state-sponsored activity with large organizations guiding research, such as the Royal Society of London (begun in 1660) and the Paris Academy of Sciences (begun in

1666). These societies sponsored a new kind of scientific expedition that was designed not merely to gather general information, but to solve specific scientific problems.

French voyages to the South Atlantic, such as that of Bouvet de Lozier in 1738, were aimed at determining the existence and location of the fabled Terra Australis, a vast southern continent believed to lie just below the tip of South America and to harbor great riches. Expeditions to find Terra Australis were often scientifically motivated, in the hope of discovering new species of plants and animals and illuminating the question of the spread of animal and human varieties around the globe, one of the pressing questions of eighteenth-century natural history and biology. Even more narrowly focused was the 1735 Maupertuis-Lacondamine expedition to discover the exact shape of the Earth. This voyage, sponsored by the Paris Academy of Sciences, was the product of a scientific controversy between the followers of the French philosopher and physicist René Descartes (1596–1650), whose theories predicted that the Earth was slightly smaller around the equator than around

the poles, and the followers of Isaac Newton (1642–1727), whose new physical system implied that the Earth must instead be slightly larger around the equator. Two parties were sent to remote parts of the Earth, one to Lapland, near the North Pole, and one to Peru, near the equator, to measure the Earth's curvature at each location and thus decide which system was correct. Besides a wealth of botanical and geographical information and specimens, the expeditions returned with measurements that supported the Newtonian world system, a great experimental triumph for Newtonian physics.

Great Scientific Circumnavigations: 1750–1800

Inspired by both the scientific and imperial potential of expeditions like those of Bouvet and Maupertuis, European monarchs began to fund large-scale scientific circumnavigations beginning in the 1750s. Louis Antoine de Bougainville sailed around the world with a team of scientists trained in Paris to record the plant, animal, and human varieties of the Americas and especially the Pacific. Bougainville's voyage sparked the European image of Pacific Islanders, especially Tahitians, as an ideal human society and served as an inspiration for the three voyages of the British captain James Cook between 1768 and 1780. Cook's voyages combined the specific and general modes of scientific expedition. He first sought to observe the passage of Venus in front of the sun at Tahiti (astronomers used these observations to determine with great precision the distance between the Earth and the sun), but also had instructions to make a general scientific survey of the islands. On board was the botanist Joseph Banks, who quarreled with Cook and never traveled with him again, but who became a central figure in European botany after the voyage. Cook's second voyage aimed to finally disprove the existence of Terra Australis, circling Antarctica at low latitudes and finding nothing but ice. His third voyage aimed to find a Northwest Passage between the Atlantic and Pacific oceans, but focused on exploring the Pacific, ending with the discovery of Hawaii, where Cook was killed after a dispute with natives.

The French response to Cook's explorations was to mount a nationally sponsored scientific circumnavigation led by Jean François de Lapérouse, with unprecedented scientific preparation: four sets of elaborate instructions, including lengthy ones from the Paris Academy of Sciences and the Royal Academy of Medicine. After all trace of Lapérouse's expedition was lost in 1788, the Revolutionary government outdid the monarchy by outfitting the most ambitious navigational survey and rescue ship to date, captained by Antoine d'Entrecasteaux, which failed to find Lapérouse but nonetheless returned with the hitherto most accurate hydrographic charts of the Pacific.

The Spanish expedition under Alejandro Malaspina (1789–1794) used Spain's American colonies as a base from which to make a botanical and hydrographic survey of the entire Pacific from Alaska to Australia. At the close of the eighteenth century, the last of the great Enlightenment scientific expeditions, Lewis and Clark's survey of the American West (1800–1803), and German scholar Alexander von Humboldt's long overland journey (1799–1804) through North and South America, perfected the new mode of broadly defined scientific travel.

Discipline-Specific Voyages: 1800–1900

The nineteenth century ushered in a new form of scientific expedition that reflected the new professionalization and specialization in science itself. Probably the most famous scientific expedition of all time was the product of this shift: the voyage of the HMS *Beagle* (1831–1836) included a young naturalist who made guided observations on the specific variations of plants and animals across geographical regions. It was these observations that led the naturalist, Charles Darwin (1809–1882), to propose his theory of evolution some twenty years later, revolutionizing biology and more general thought about human origins.

The U.S. Exploring Expedition of 1838 aimed to put advances in navigation and charting to use to master the geography of the Pacific. The *Challenger* expedition (1871–1875), under the Edinburgh

Mazamboni's country bears many names. *Mtusuuma*, *Ndussumma*, *Mtagata*. His subjects are called *Bundussumma*.

April 26: Descended to Badgwa on the Lake plain in ^{the m.} 2:45

1950 feet of a descent.

Record keeping is an important element of scientific expedition. This page from the notebook Henry Stanley kept during his travels in Africa added to scientific knowledge of the region, even though Stanley was not a scientist.

marine naturalist Wyville Thomas, actually created a new discipline: oceanography. Sparked by a debate over how deep in the ocean life could exist, *Challenger* took advantage of new dredging techniques to study all facets of ocean life.

Astronomy had long been a component of travel, and astronomers were frequent members of scientific expeditions, but in the late nineteenth century a wave of support grew for specifically astronomical expeditions, especially those to observe solar eclipses. When photography was introduced into astronomy around 1870, it became a key element in transporting scientific information from the expedition site to

the sponsoring country or laboratory. Expeditions such as Norman Lockyer's to Bekul, India, to observe the solar eclipse of 1871, were central to the rise of nationally funded science in Britain and took advantage of its growing colonial empire.

Many of the key figures in creating government support for all kinds of science in Britain were themselves planners of eclipse expeditions. By the late 1800s, national scientific styles began to strongly influence astronomical travel: British and French expeditions depended on highly centralized funding, while U.S. expeditions were locally organized and funded, usually by a university or observatory.

The Final Frontiers: 1900–Present

With the dawn of the twentieth century, the focus of scientific travel shifted once again to geographical exploration, this time in the last regions of the globe left unexplored. The Canadian Arctic Expedition of 1913–1918, led by Vilhjalmur Stefansson, marks the beginning of this trend. Stefansson's goal was to cross the Beaufort Sea and study the balance of earth, ice, and water at the edge of the polar ice cap. He was trained as an anthropologist and had spent winters with the Eskimo of northern Canada. After only a month of travel, the largest of his three ships was stuck in ice and soon crushed in a storm, together with half the supplies for the expedition. Stefansson and a small group pushed north using dogsleds and Eskimo hunting techniques; the breakaway party managed to gather scientific observations on much of the Beaufort Sea, discovering five new islands, and remapping many of the coastlines. Reunited with the rest of the expedition at Cape Kellett, they continued their polar exploration and data gathering for another three years before returning with a wealth of new information and launching a century of scientific polar expeditions.

After World War II, Asia came once again to prominence in science and scientific expeditions. The same drive to reach the last frontiers of scientific study on Earth pushed a Japanese team to map the fauna and flora of the Nepal Himalaya in 1952–1953. This expedition displayed the dawning international

character of scientific expeditions: while all the members of the exploration party were Japanese, the specimens they gathered were sent to specialists around the world for identification and analysis.

While both the Canadian and Japanese expeditions relied on local, traditional methods to survive extreme conditions, new technologies in the second half of the twentieth century were also crucial in allowing expeditions to penetrate previously inaccessible realms. Beginning in the 1950s, underwater submersible devices allowed explorers like Jacques Cousteau to continue the investigation of oceans to a depth and in detail unimaginable fifty years earlier. Similarly, since the early 1960s space exploration based on the fueled rocket and computer controls has defined a new frontier for scientific expeditions.

New Frontiers in Scientific Expeditions

As scientific expeditions move beyond the Earth, specialization of scientific disciplines has culminated in research projects developed and carried out by teams of specialists at home. Projects based on one national style of organization and funding are giving way to cooperative, international ventures in which teams from different countries provide specialized contributions. Yet for all its novelty, space exploration still displays the enduring and unique combination of forces that has characterized scientific expeditions since antiquity: the desire to go beyond the traditional human boundaries and the need to rely on disciplined observation to tame the profusion of information encountered in unknown lands; the tension between the drive for national prestige and the desire to see science, especially scientific travel, as transgressing all political boundaries; and finally, the belief in the unique potential of science to guide the quest for knowledge of the unknown.

Exploration, Chinese

China focused mainly on inward expansion throughout much of its history, and most of its seafaring took place in their coastal waters and the Indian Ocean. The most famous Chinese ocean explorer is Admiral Zheng He, who undertook seven expeditions over three decades during the Ming dynasty (1368–1644). Unlike many European explorations, Chinese exploration was not motivated by Chinese colonial expansion.

Much important exploration has occurred through sea voyages, which were a starting point for a form of globalization in the early modern era of world history. While European and Western explorers more generally have received much attention, the Chinese were also active in exploration. A land-based nation, China is also surrounded by four seas: the Bo Hai Sea, the Yellow Sea, the East China Sea, and the South China Sea, which link China to the Pacific and Indian oceans. Mainland China has favorable conditions for sailing in terms of the climatic patterns: sea and ocean currents, tidal patterns, and inland transportation to the coast.

In addition to maritime exploration, during the Han dynasty (206 BCE–220 CE) overland Chinese explorers, such as Zhang Qian, made contact with kingdoms in Central Asia, India, Persia, and the Middle East. It is thought that Gan Ying, an emissary of General Ban Chao, might also have ranged as far as Roman-era Syria late in the first century CE. And while the Silk Roads continued to connect China to the outside world and remained a key source of trade, soon China's exploratory efforts would turn more exclusively towards the seas.

China's Three Early Sea Routes

China's maritime activities have undergone a long evolution. Although scholars have debated when and how Chinese maritime exploration began, and how just much Chinese sailors achieved in their premodern era (ending around 1840), the extent of China's maritime undertakings can be seen from the sea routes that Chinese sailors used. There were three types of routes: local short-range routes along China's own coast; medium-range routes to eastern Asia, southern Asia, and Southeast Asia; and long-range routes to western Asia and eastern Africa.

By the Western Han period (206 BCE–8 CE), it is recorded that Chinese ships reached as far as Simhala (now Sri Lanka). In the Eastern Han period (25–220 CE), Chinese ships went beyond Sri Lanka to reach destinations in western Asia. In 97 CE, Gan Ying, the Chinese envoy designated to the Roman Empire, went as far as the edge of the Persian Gulf. From the Tang dynasty (618–907 CE) onward, some of these sea routes were frequently used by the Chinese, the Indians, and Arabs; they formed the so-called Silk Routes (as compared with the overland Silk Roads).

Maritime Growth Begins

By the tenth century, most of the sea routes used by the Chinese followed coastlines. Major maritime progress was made during the Song dynasty (960–1279), when China experienced its medieval economic revolution. For the first time, Chinese ships were able to cross some 2,300 kilometers of open waters in the Indian Ocean from Malacca to Sri Lanka, avoiding the coastal detour in the Bay of Bengal. They even

sailed from Sri Lanka to Ghubbat al Qamar, an inlet of the Arabian Sea on the Arabian Peninsula, across another 4,000 kilometers of ocean. This was a huge leap in Chinese maritime advancement.

With ongoing incremental improvements in technology, the Chinese sailed faster and more accurately. As a result, sea voyages became progressively shorter. In Western Han times, a trip to the vicinity of Singapore took some 150 days, but the same journey took only 40 days during the Song dynasty. During the Sui (581–618 CE) and Tang (618–907 CE) dynasties, it took more than a month to travel from Sri Lanka to the Persian Gulf, whereas by the Ming dynasty (1368–1644), to cover a similar distance took just twenty or so days.

Central to Chinese progress in sailing were improvements in navigation and shipbuilding. Astronomical navigation became well established in China by the end of the ninth century, and it was enhanced by the invention and use of the compass during the tenth century, which led to the stage of partial dead reckoning, that is, navigating in part without reliance on the stars, using measured travel distance and compass positions instead. In time, sophisticated seaway compass charts became available among Chinese navigators; these contained information on main landmarks, star elevations at chosen locations in different seasons, travel distances, and compass readings for various sea routes. A good example is *Zheng He hanghai tu* (The Navigation Chart of Zheng He's Voyages), from the fifteenth century.

In terms of shipbuilding, Chinese technology reached its maturity by the twelfth century with the Fuzhou-type ship (*fuchuan*), which was used exclusively for sea voyages. Its main features were a ballasted keel and bilge keels together with a low deck length-beam ratio for stability; a V-shaped bottom and multiple sails and jibs (three to twelve as recorded) for speed; multiple stern rudders for steering; and a hull of clinker-arranged planks with multiple holds for a stronger structure. During the same period, the versatile shallow-water ship (*shachuan*), commonly known as the Chinese junk, was also invented; its distinctive features were a keel-less hull and a U-shaped

Chinese Admiral Zheng He's astronomically guided chart from Ceylon to Sumatra.

bottom. The Fuzhou-type was the standard for the Ming fleet.

By the mid-fifteenth century, the Chinese were among the most knowledgeable, best-equipped, and widest-traveled sailors in the world, having come by 1440 to a total of 153 new places in such geographically dispersed regions as Southeast Asia, South Asia, the Arabian Sea, the Red Sea, the East African coast, and even the Mediterranean region.

Ming Voyages: Glory and Outcome

Undoubtedly, the best-known recorded case of Chinese exploration was that of Admiral Zheng He (1371–1433). Without Zheng He and his publicized seven voyages to the Indian Ocean, much of Chinese maritime ability and achievements may have been obscured in history, as happened with the Polynesians.

A sailing ship typical of those used in Chinese explorations in the Indian Ocean.

Recruited as a young eunuch to enter the inner circle of the Ming Court, Zheng was appointed in his early thirties to command a long ocean-going voyage in 1405, despite the fact that he had no apparent sailing experience. It appears that Zheng's constant sailing for the next three decades (until 1433) served the Ming court the purpose of keeping him away from state politics—a dignified way to achieve his exile following his involvement in a court coup. In this context, there was an element of sailing for the sake of sailing associated with Zheng's journeys, all of which resulted in economic losses for the Ming dynasty. Nor did Zheng He's voyages lead to greater prosperity in foreign trade, which might have let the court recoup the cost of the voyages.

In reality, the sole purpose of the ill-defined voyages was as a public relations campaign to win friends for China overseas. Indeed, Zheng and his men behaved like philanthropists, distributing gifts wherever they went. Even so, the actual effectiveness of the campaign remains highly questionable. The number of countries that paid tribute to the Ming increased very little during and after Zheng's voyages. The main evidence that “international peace” was promoted by Zheng's visits comes from the fact that Zheng set up four regular stopovers in Champa (in present-day southern Vietnam), Sumatra, Sri Lanka, and Guli (Calicut in present-day India) instead of turning these places into China's colonies.

Spectacular as they were, Zheng He's multiple-legged trips were by no means unprecedented in

Chinese diplomacy: twelve centuries earlier, during the Three Kingdoms period (221–265 CE), Sun Quan, the King of Wu, sent Zhu Ying and Kang Tai overseas for a twenty-year diplomatic mission, during which time they visited Southeast Asia, the south Asian subcontinent, and the Arabian Sea region. Similar efforts were made during Yuan rule (1279–1368). And Zheng He was not alone in his adventuring during the Ming: another navigator, Shi Jinqing (d. 1421), toured Asia as imperial commissioner, traveling at least as far as Sumatra, Java, and Japan.

Due to the unclear motives, extravagant nature, and doubtful impact of Zheng's voyages, the Confucian literati during the Ming did their very best to ignore them. Zheng's records survived only in the hands of his closest aides, Ma Huan and Fei Xin, in the form of travelogues entitled *Yingya shenglan* (Tours to Great Sites Overseas) and *Xingcha shenglan* (Voyages on Heavenly Rafts), written in 1451 and 1460, respectively. Since then, most of Zheng's findings have remained unknown to the large majority of the Chinese population.

However, the sheer scale of Zheng's operation shows China's organizational skills and accomplishments in the maritime sector: as many as 208 vessels and around 28,000 marines were involved in a single voyage, taking multiple sea routes simultaneously with detachments in order to maximize geographic coverage. It has even been suggested that Zheng's detachments may have visited Australia and parts of America across the Atlantic Ocean.

In the end, Zheng's voyages proved to be unsustainable. Cool-headed cost-benefit calculation finally prevailed among Confucian decision makers, and such wasteful voyages were never undertaken again. Chinese sailors during the Qing dynasty (1644–1911/12) were content to remain within the China seas. In a twist of historical fate, this made Zheng a legend and his journeys the pinnacle of Chinese maritime history; Zheng achieved a worldwide record that was only broken by Europeans with different political and economic institutions and agendas, as seen from the activities of Christopher Columbus and Vasco da Gama.

Do not fear going forward slowly; fear only to stand still. • Chinese Proverb

Historical Perspective

China's achievements in exploration over the long run (from the beginning of the Han in 206 BCE until the end of Zheng's journeys in 1433 CE) were significant by premodern standards. But, as in many other areas, upon turning inward the Chinese were surpassed by the post-Renaissance Europeans, who enjoyed the fruits of the scientific revolution, the military revolution and, finally, the Industrial Revolution. All of these revolutions took place after Zheng's era.

Ironically, during the late nineteenth century when the Chinese took to the sea again in large numbers, they were no longer accomplished mariners on showy Chinese treasure ships. Rather, they were helpless coolie laborers on foreign ships on the way to sell their cheap labor to the West, showing just how poor and weak China had become since Zheng's time.

Extinctions

Extinctions have occurred throughout the history of the Earth; extinction is in fact a critical component in the theory of evolution and is attributed to natural selection, random factors, or catastrophic events. The Earth has survived five mass extinctions—including one that destroyed the dinosaurs—all of which have shaped the world as we know it today.

The fossil record reveals that the history of life has been a process of speciation, or the diversification of organisms into new species, accompanied by extinction, or the disappearance of existing species. Speciation and extinction are equal partners in evolution. In neo-Darwinian theory, genetic variation and natural selection are the primary agents in evolution. Natural selection favors genetic variation that improves an organism's chances of surviving to reproduce within its environment. Successful variation is passed on to the next generation. Its frequency in the population increases from generation to generation until it eventually replaces the earlier, less advantageous trait. Acquisition of new traits sometimes enables organisms to invade new habitats. In neo-Darwinism, the environment is the prime source of selection. Therefore, environmental change—or change of environment, in the case of habitat invasion—is considered the chief cause of species evolution. New environmental conditions change selective pressures operating on populations of organisms. Populations must adapt to new circumstances or perish without descendants. In addition to natural selection, random factors and rare, catastrophic events also appear to play a role in extinctions.

Earth is some 4.6 billion years old. Geologists divide this time into eras, periods, epochs, and

ages. (See table 1.) Life first appeared on Earth late in the Precambrian era some 3.5 billion years ago. The majority of species that evolved since that first appearance are now extinct. Through time, species generally disappear individually in “background extinctions.” But during at least five mass extinction events, huge numbers of species perished together over (geologically) short spans. (See table 2.) By eliminating some previously successful species and allowing other, formerly minor, groups to expand and diversify, each mass extinction restructured the biosphere.

End-Cretaceous Extinctions

The Cretaceous (114 to 65 million years ago [mya]) was the final period in the age of dinosaurs. At its

Table 1.
Geological Time Scale

Eras	Periods	Epochs
Cenozoic (65 million years ago [mya] to present)	Quaternary	Holocene
Pleistocene	Tertiary	Miocene
Oligocene		Eocene
Paleocene	Mesozoic (248 to 65 mya)	Cretaceous
Jurassic		Triassic
Paleozoic (540 to 248 mya)	Permian	
Carboniferous		Devonian
Silurian		Ordovician
Cambrian		Precambrian (4.6 billion to 540 million years ago)

The “Big Five” Mass Extinction Events in Geological Time

End-Cretaceous period	c. 65 million years ago (mya)
Late Triassic period	c. 210 to 206 mya
Late Permian–Early Triassic period	c. 252 to 245 mya
Late Devonian period	c. 364 to 354 mya
Late Ordovician period	c. 449 to 443 mya

close, virtually all of these great beasts—together with more than 50 percent of Earth’s species—disappeared suddenly and entirely. Many scholars attribute their extinction to climate change, but the disappearances were not gradual, and the dinosaurs appear to have been diversifying up to the end. The physicist Luis Alvarez and his colleagues (1980) note that rock layers dating to the Cretaceous boundary commonly contain a thin clay layer of iridium, a rare metal resembling platinum, and spherules or tektites, spherical bits of glassy rock formed from molten silicate droplets. They interpret this as evidence that one or more mighty asteroids or comets struck Earth around 65 million years ago. They hypothesize that the impact generated a giant vapor cloud (out of which the spherules condensed), sent shock debris across the globe, created an immense fireball, and cast a huge plume of dust into the atmosphere. As this dust plume ascended, atmospheric winds spread it into a globe-embracing cloud that blocked sunlight from the Earth’s surface for a year or more. In this scenario, mass extinctions resulted from both the initial impact and the disruption of the food chain that followed. Perhaps the collision also ignited vast global fires that added huge smoke plumes to the sun-blocking haze of the windblown impact debris. A crater between 200 and 300 kilometers in diameter of the proper age and aspect that has been identified in the subsurface of the Yucatán Peninsula of Mexico may be the impact point. Asteroid collisions may have caused the earlier mass extinctions of the Late Devonian, the Permian–Triassic, and the Late Triassic as well. Whatever its cause, the Cretaceous extinctions ended the dinosaurs’ domination and provided empty ecological space that was ultimately filled by the mammals, a hitherto insignificant class of vertebrates.

Pleistocene/Holocene Extinctions

The Pleistocene epoch (1.8 mya to 8000 BCE) was preceded by the Pliocene and followed by the Holocene epoch (8000 BCE to present). It is called the Ice Age because continental-scale glacial ice sheets cyclically advanced and retreated during this time. Near its close, anatomically modern people (*Homo sapiens sapiens*) evolved, probably in Africa, and spread throughout most of the Earth. Although background extinctions occurred throughout the epoch, Pleistocene animal life remained rich. Then, between 10,000 BCE and 6000 BCE, extinctions occurred on a massive scale. “Megafauna,” species with large adult body sizes and body weights over 45 kilograms (100 pounds), were most severely affected.

Although extinctions occurred on all continents, they did not occur on them uniformly. The number of megafaunal species that disappeared in the New World was much higher than elsewhere. During the 4,000 years after 10,000 BCE, North and South America lost the Colombian mammoth, mastodon, horse, camelops, Shasta ground sloth, saber-toothed cat, and seventy other genera. Extinction rates in Europe and Eurasia were lower. Nonetheless, the woolly mammoth, woolly rhinoceros, Irish elk, and other cold-adapted creatures disappeared after 14,000 BCE. Musk oxen, steppe lions, and hyenas disappeared there but survived elsewhere. The distribution of horses and steppe bison became greatly restricted. Late Pleistocene extinction rates were lowest in Africa. Megafaunal extinctions that occurred there, frequently at the beginning of the epoch, were modest in number at its close.

What Was the Cause?

Rapid climate change at the Pleistocene’s close is a possible cause. During the last 128,000 years of the epoch, the Northern Hemisphere experienced long continental glacial advances punctuated by short-term ice contractions or interstadials. Glaciation terminated abruptly about 10,000 BCE and was followed by rapid deglaciation and a warmer, moister climate. During this interstadial, European, Eurasian,

F. John, *Dodo oder Dronte* (1890). Color illustration. The dodo bird (*Raphus cucullatus*) is considered by scientists to be the “poster bird” for extinction.

and North American forests expanded northward, severely curtailing the range and population sizes of plains megafauna like the horse, mammoth, bison, and woolly rhinoceros. This interstadial ended about 9000 BCE, and glacial conditions returned for another thousand years. Extinctions were not entirely coeval with this deglaciation, however. Further, rapid climatic changes had occurred often during the Pleistocene without triggering similar waves of extinction. Presumably, most Pleistocene species had evolved physiological tolerance for climatic change or could migrate in the face of it. Further, some species, most notably the horse, became extinct in North America but survived in Eurasia to be reintroduced to the New World in historic times. If the environment of North America had been fatal to the horse at the end of the Pleistocene, would the wild descendants of Spanish mustangs be able to roam the western United States with such success today?

While climatic change cannot explain the Pleistocene extinctions, perhaps “anthropogenic overkill,” human hunting on a limitless scale, does. Two kinds of evidence suggest this: (1) the asymmetry of worldwide extinctions and (2) the stratigraphic association between human stone tools and the bones of extinct species. Variation in the pace of extinction in Africa, Eurasia, and the New World may reflect the different arrival times of fully modern humans on each continent. Megafauna and the hominids evolved together in Africa over the last four to six million years and anatomically fully modern *Homo sapiens*

probably evolved there some 150,000 years ago. Some suggest that the extinction rate of African megafauna was low by the terminal Pleistocene because the species had evolved behavioral means of coping with human predation by that time. Anatomically fully modern *Homo sapiens sapiens* did not appear in Europe until around 35,000 years ago. The shorter period of association between European game animals and these new human predators may account for the greater rate of megafaunal extinctions in Europe compared to Africa.

The stratigraphic association between the stone tools and the bones of extinct megafauna found in the terminal Pleistocene age archaeological sites is also taken as evidence of human “overkill.” The vast quantities of mammoth bones recovered from the celebrated kill sites in the Ukraine indicate Eurasian hunters slaughtered prodigious numbers of these beasts there. Such evidence is strongest in North America where direct and primary association between the distinctive lanceolate-shaped Paleo-Indian stone projectile points and megafauna is well documented. In North America, the extinction of key elements of Pleistocene megafauna, including ground sloths, camelopes, tapirs, mastodons, various species of bison, mammoths, and horses between 10,000 and 8000 BCE is clearly correlated with the abrupt appearance of the Paleo-Indians between 9500 and 9000 BCE. If the specialized Paleo-Indian hunters were the first people to arrive in the New World, they would have found a hunter’s paradise filled with game but empty of

There is little doubt left in the minds of professional biologists that Earth is currently faced with a mounting loss of species that threatens to rival the five great mass extinctions of the geological past. • Niles Eldredge (b. 1943)

human competitors. That paradise would have been unlike anything in the Old World as the animals in it had not evolved the behaviors they needed for dealing with cunning, two-legged human predators. As Paleo-Indian peoples grew in number, they would have expanded southward and across the continent in an advancing wave. By employing game drives and other wasteful hunting strategies that indiscriminately killed large numbers of game, these early hunters may have extinguished megafauna on an ever-widening front. It seems plausible that anatomically modern humankind—practicing predation on the large and profligate scale reflected at kill sites like Solutré, Dolni Vestonice, and Olson-Chubbuck—tipped the balance against megafauna already stressed by changing climate. If these sites do indeed reflect human connivance in “megacide,” they provide a cautionary tale: once destroyed, species do not come back.

The extinction of the megafauna must have forced big-game-hunting peoples to realign their subsistence. The archaeologist Mark Cohen (1977) asserts that, by reducing available game, the extinctions initiated a “food crisis” after around 8000 BCE that forced people in Eurasia, Europe, Africa, and the Americas to expand their subsistence bases and exploit a greater range of species and habitats. Hitherto neglected species like fish, crabs, turtles, mollusks, land snails, migratory waterfowl, and rabbits became a routine part of the diet, and plants were exploited systematically for fruit, tubers, nuts, and seeds. Ultimately this food crisis may have stimulated the development of agriculture.

Late Prehistoric and Historic Period

Extinctions at the hands of humans continued in the late Prehistoric and Historic periods through (1) habitat fragmentation and destruction, (2) the introduction of predators or foreign competitors (particularly on islands), (3) overhunting, and, more recently, (4) hunting or gathering wild organisms for market sale. By late prehistory, few of the world’s habitats had not felt the impact of humankind. Nonetheless, all impact was not the same. While that of the hunter-gatherers was modest, agricultural

systems transformed the landscape. Extinction of species through habitat loss has chiefly been due to the spread of agriculture and the competition between indigenous fauna and domestic animals. Yet domesticants are not the only new arrivals that generate extinctions. On islands, numerous bird species have vanished following the human introduction of rats, mongooses, or snakes. The brown tree snake, brought to Guam around 1950, extirpated nine of the thirteen native forest birds on the island. Species extinction has also resulted from intentional human persecution. A dramatic example is found in the archaeological record of New Zealand. Long isolated from mainland Asia, New Zealand supported a unique array of large, ground-dwelling, flightless birds called moa. Moa species ranged from the size of turkeys to giant, ostrich-like creatures ten feet or more in height. Having evolved in the absence of predators, they probably had little fear of the Polynesian colonists who probably arrived on the island sometime in the thirteenth century. Within one hundred years, the eleven species of moa had been hunted to extinction.

Human persecution is especially likely to result in extinction when species are exploited for the market. The passenger pigeon inhabited eastern North America in uncounted numbers; their migrations darkened the skies for days. In the nineteenth century these birds were systematically harvested for market, and the species was extinct by 1914. Similar fates befell the great auk, the dodo, and numerous other bird species. An equally grim fate faces chimpanzees and gorillas, currently sold as “bush meat” in parts of Africa. Rhinoceroses are nearly extinct because ground rhino horn is regarded as an aphrodisiac in Asia. Marine fisheries worldwide are threatened by systematic market and sport fishing. Future extinctions may include cod, tuna, blue marlin, swordfish, and some species of whale. The dismal list goes on and on.

Extinction Matters

Extinctions have affected world history profoundly. First, the mass extinction of the dinosaurs at the end of the Cretaceous period allowed the diversification of

Thylacinus in the Washington D.C. National Zoo circa 1906. Scientists believe the thylacine became extinct during the 1900s. Photo by E. J. Keller, Smithsonian Institution Archives.

the mammalian order and, ultimately, the evolution of humans. That distant extinction event marks the nascent beginning of human history. Second, by forcing great changes in subsistence, the great extinctions in the Late Pleistocene may have triggered a “food crisis” that led to agriculture. Third, Late Pleistocene extinctions greatly impoverished the fauna of the New World. In the absence of key domesticable animal species, New World agriculture came to be based on plants. Old World peoples, living in an environment less impoverished by extinctions, domesticated many animal species and, as a result, were plagued by zoonoses, infectious diseases like smallpox and flu derived from them. As long as they remained isolated from the Old World, Native Americans remained free of such diseases. Following the arrival of Europeans and Africans, however, their lack of exposure and immunity laid them open to massive “virgin land infections” that contributed directly to their defeat and large-scale genetic replacement by peoples from the Old World. Late Pleistocene animal extinction patterns thus helped to determine the human population makeup of the Americas.

A Sixth Mass Extinction?

Present rates of extinction appear to be between 1,000 and 10,000 times the rates seen through most of geological time. The possibility of global warming darkens the picture further as changing climatic

patterns may cause extinctions by disrupting species distribution and abundance. Is the world on the brink of a *sixth* mass extinction event? And, if so, can anything be done to avert it? In the near term, international efforts at saving such critical habitats as the world’s forests and ocean fisheries must be intensified. Introduction of foreign species into new environments must be curtailed and the protection of endangered species increased. Such protection is never cheap or easy, but experience with the California condor, the sea otter, the American bison, the whooping crane, and other species indicates that it can be done. Simultaneously, zoos and aquariums must act decisively to breed endangered species in their charge. Reproductive and developmental biology can help. Genome banking of sperm from endangered species is promising as are more experimental approaches like somatic cell cloning. Chinese biologists are seeking to increase giant panda populations using nuclear transfer techniques involving bears as egg donors and surrogate mothers. Attempts at genetically restoring vanished species like the Tasmanian tiger and the mammoth are in the offing.

Whatever we do, we must recognize that extinctions in the present age are caused by the inordinate success of our own species. Therefore, controlling our populations and bridling our destructive impulses are essential. Global economic underdevelopment intensifies both of these problems. Poor people do not kill rhinoceroses or hunt endangered apes out of malice.

They do so to relieve their poverty. Stopping these practices demands eliminating the economic inequalities that necessitate them. No small task this, but, if we fail in it, the final impact of extinction on world history may be the elimination of our own species.

Famine

Throughout history people have experienced food shortages and famines. Only in relatively recent times has agricultural development progressed to the extent that sufficient accumulated food stocks could allow for the possibility of eradicating world famine. The fact that famines do still occur is not a consequence of insufficient food, but of political and social problems, including those associated with local distribution.

Famine is a complex social phenomenon and is distinguished from starvation by its social aspect. Individuals starve to death as a result of reductions in food supply, but societies experience a more complex response. Not all members of society suffer equally from food shortages. As Amartya Sen has pointed out, the poorer and less privileged sections of society, whose entitlements to food are least secure, suffer more than the richer, more privileged sections. The history of famine is not simply a history of factors that cause a reduction in food supply, or of the imbalance of food production against population growth. It includes the history of social and political responses to these problems, the history of social formations, and the history of social differentiation concerning food entitlement. While there has traditionally been a classification between natural and politically induced famines, the distinction does not really hold. Every famine that develops to take on significant mortality consequences indicates a failure of famine avoidance and relief measures. Most famines have had multiple causes.

All previous social formations have experienced food shortages and famines. It is only in relatively recent times that agricultural development has progressed to such an extent as to enable sufficient food

stocks to be accumulated to pose the possibility of the eradication of world famines. The fact that famines do still occur is no longer a consequence of there being insufficient food, but of political and social problems including those associated with local distribution.

Famine in Early Social Formations

At earlier times there had not been a progressive move toward the eradication of hunger. The shift from hunter-gatherer to settled farmer societies was not associated with improved nutrition. The anthropologist Mark Nathan Cohen has assembled anthropometric data that indicates that early settled society was more vulnerable to food shortages, and he argues that starvation from this time may have been associated with political and economic issues more than with agricultural events. There is evidence in the earliest civilizations in Egypt, China, India, the Middle East, and classical Europe of considerable concern over food supplies and the establishment of large state granaries and famine relief and transportation systems.

In China the granary system dates back to antiquity and the tribute system was well developed before the Grand Canal was opened in 611 CE linking the Huang (Yellow) River in the north with the Yangzi (Chang) in the south. Part of this supply system was destroyed by the Mongol invasion of the thirteenth century, and imperial food supply problems were complicated when first Khubilai Khan and then the Ming emperors established the capital at Beijing in the north rather than in the Huang River basin at Xi'an (Chang'an) or Luoyang, or at Nanjing on the Yangzi. In 1325 there was a massive famine that is claimed to have killed between 4 and 8 million people. Faced with

A group of children deserted by their parents line up with caregivers in the Volga district of Russia, blighted by famine circa 1921. Library of Congress.

this challenge, the rulers revived the tribute system, granaries, and famine relief work and developed them to a new level. In the great drought of 1740–1743, at a time when the European subsistence crises were still causing a substantial number of deaths, the scale of Chinese famine relief was enormous and mass mortality was largely avoided. By the early part of the nineteenth century about 400,000 tons of grain a year were transported through the tribute system to feed the northern garrisons and a Beijing population of 800,000. Although the granary system began to decline from the time of the White Lotus Rebellion at the end of the eighteenth century, transport on the Grand Canal probably peaked in the first half of the nineteenth century, on the eve of the First Opium War (1839–1842), before the British cut this vital supply link and plunged the country into turmoil and a period of famine and rebellion.

There is some dispute as to how efficient the Chinese Empire was in the period before the troubles of the nineteenth century. Modern scholars argue that living standards were much higher than in Europe until the time of modern imperial troubles.

India under the Mughals had also developed successful ways of dealing with famines before the British advance into India following Clive's victory at the Battle of Plassey in 1757. It was under British rule that economic growth slowed below the rate of population growth and per capita living standards fell to dangerous levels. There were few signs of major famine in

India before the Great Bengal Famine of 1770 under the administration of the East India Company.

As the classical urban population of the south of Europe grew in size, more grain had to be imported into these regions and the authorities became increasingly concerned about establishing granaries and other food support systems. Governments provided support to assist the transportation of grain into the major cities. Famines would occur when there was a breakdown in these supplies.

The European population then spread to the colder less hospitable areas to the north, where, given the technology of the time, the population was more vulnerable to the influence of the weather. The greatest recorded European famine was experienced in northern Europe from 1315 to 1322. Modern scholarship tends to question the Postan thesis, which presumed the existence of overcropping and soil exhaustion throughout a very large area of northern Europe. The exceptional damp weather for a number of years appears to have been the main factor. The result was massive social disturbance, food deprivation, and high mortality levels. The weakening of this generation may have contributed to the continued massive population losses from the Black Death a few decades later. Together the sharp population losses of these years appear to have caused a change in the relative values of land and labor, which probably contributed to the weakening of feudal relations and the growth of more commercial ones.

In this drawing from the late nineteenth century, Chinese farmers affected by famine take their house apart to rebuild it in a more auspicious location.

Subsequently European famines have never been so severe, although periodic subsistence crises would produce smaller-scale famines periodically down to the eighteenth century in many areas. The last of these great peacetime subsistence crises in the northern and central regions of Europe occurred in the early 1740s. The situation was worse in the extremities of Europe with major famines in Finland in 1696–1697, in Ireland in the 1840s, and in Russia in 1871, 1891, and into the twentieth century. The rest of the world experienced similar problems, but with the period of subsistence crises lasting much later, and with larger amounts of disruption to the traditional supply systems as a result of wars and colonial expansion.

Western colonialism is no longer seen as a benign process of modernizing the uncivilized world. There is a growing realization of the costs of the destruction

of the local domestic economy and of the traditional coping practices, which made it difficult for these societies to respond adequately to the serious natural and political challenges that they faced at this time. The serious famines of the 1880s and 1890s in India, China, South America, and Egypt are presented rather provocatively as “Victorian Holocausts” (Davis 2001) in which colonial administrators hindered the local government from responding to the challenges in the El Niño Southern Oscillation.

Twentieth-Century Famines

During the two major world wars of the twentieth century, both sides attempted to disrupt their enemies’ food supply channels and to cause famine and social disruption. The rationing and food securing operations of the main developed countries largely succeeded in avoiding this outcome. In several of the poorer countries in central and Eastern Europe and Asia, however, there were very serious consequences. Americans provided large amounts of food and famine relief to Belgium throughout World War I and to large areas in central and Eastern Europe and Russia after both of these wars. This did largely contain the crisis in these areas. There was, however, a major famine in Russia in 1921–1922, which was partly related to the continuation of civil war following World War I and the revolution. During World War II there was a famine in the occupied Greek islands, in the Netherlands after the Battle of the Bulge in 1944, and throughout the war in occupied and besieged parts of Eastern Europe and Russia. The famine in blockaded Leningrad is perhaps the best-known case.

In Asia World War II contributed to serious famines in China (1937–1945), India (Bengal, 1943), and Vietnam (1942–1944). In subsequent years famines have often accompanied minor military engagements between poorer countries.

There has been much controversy over the relationship between famine and Communism. While it is true that the three major famines of the twentieth century (USSR 1921–1922 with 3 million deaths, USSR 1930–1933 with 6 million deaths, and China

Man can and must prevent the tragedy of famine in the future instead of merely trying with pious regret to salvage the human wreckage of the famine, as he has so often done in the past. • **Norman Borlaug (1914–2009)**

1958–1961 with 15–20 million deaths) all occurred in Communist countries, it is somewhat superficial to blame these famines on Communism per se. Both Russia and China had frequently suffered from famines before they became Communist, and in both countries the Communist revolution had taken place during and following a period of major economic collapse that had been associated with major famines. In China this was the extended period of troubles from the 1850s to 1948; in Russia it was a shorter period, from 1917 to 1922. During these troubled periods the major cities experienced extensive famines as the state structure weakened and the traditional supply system broke down. The successor revolutionary states that were born out of these troubled times were anxious to develop the economy and rebuild supply structures.

In the railway and industrial age there appeared to be great prospects for these states, which both experienced remarkable growth in the first decades of their revolution. In both cases the second decade brought about excessively ambitious plans to escape from the poverty trap, which in combination with unexpected poor weather led to the onset of a series of factors that resulted in the largest famines of the twentieth century. Attempts were made by both regimes to conceal these “Great Leap” famines and to deny their existence. It was only years later that the true scale of these disasters became apparent.

Despite these early Communist disasters, the USSR and China did develop their economies and industrialized to a certain extent. They have proved to be no match for the advanced Western economies, but their experience in central planning was for a while highly popular in the newly independent former colonies, which were also looking for a way of industrializing in a hurry. It is the underdeveloped world that has failed to industrialize that continues to experience famine, especially in sub-Saharan Africa.

There are some scholars who claim that the Great Irish Famine of 1841–1845 and the Russian famine of 1931–1933 were both cases of genocide in which a major colonial power, Britain or Russia, attempted to weaken and control a troublesome region. Although in both cases the colonial power can be accused of

acting insufficiently vigorously to reduce the famine, there is little evidence to support the case that these famines were caused on purpose.

Famine and Disease

Before the late nineteenth and early twentieth centuries famine had always been associated with major epidemic diseases, often typhus. Relatively few people had died from starvation, because other epidemic diseases killed them first. This applied to the Great Irish Famine of 1847, the Russian Famine of 1921–1922, and the Bengal Famine of 1943. But epidemic diseases have played a less important role in subsequent famines and especially in the Soviet Famine of 1931–1933 and the Chinese Famine of the Great Leap Forward, 1958–1961. We are now in a new age of famine demography in which simple medical and sanitary intervention can greatly reduce the likelihood of death from disease. Unfortunately, this has not resulted in an absence of great mortality in famines. It has, however, reduced the scale of mortality, which otherwise would have been considerably greater.

Outlook in the Twenty-First Century

The Malthusian threat of population growth outstripping growth in food supplies has failed to be realized in the twentieth century and is unlikely to emerge in the twenty-first century.

The threat of major world wars to cause famines by disturbing major supply channels also failed to emerge in the major countries in the twentieth century, although it has been an important factor in smaller poorer countries. It would be extremely rash to presume that any major conflict in the future would have a similar result. Disruptions in food supplies to the underdeveloped world are unfortunately continuing. Famine will remain a major challenge to the world in the twenty-first century, despite the ability of the world to produce food surpluses.

Fascism

Mussolini invented the name *fascism* for the regime he inaugurated in Italy after World War I. Hitler subsequently adopted it for his Nazi movement, and similar militaristic and reform movements in other countries are often called fascist, too. A core fascist idea was that national interests ought to override everything else; and that war or preparation for war was essential for national survival.

What is fascism? That is a question that has been debated since its appearance in the turbulent years following World War I. Defining what fascism is and, just as importantly, what it is not is crucial not only for understanding movements that appeared in the twentieth century, but also those that may arise in the twenty-first.

It is a common mistake to label any tyrannical, or seemingly tyrannical, political entity or individual as *fascist*. This applies both to premodern dictatorships and to more recent military dictatorships, which, while they may be authoritarian and oppressive, are not fascist. For while the few fascist movements that actually achieved power, such as in Italy and Germany, have been more or less tyrannical, most of the world's tyrants have not been fascists, for they do not adhere to the core beliefs of the true fascists, such as a strident antiliberalism, anticonservatism, and especially anticommunism.

A more difficult delineation can be made between fascist movements and authoritarian regimes. The concern of authoritarians is to create a strong and stable nation and they usually do not alter society in any appreciable way. While these governments may espouse some tenets of fascism, such

as anticommunism, they generally leave traditional elite structures—powerful regional families, church officials, military leaders, and entrenched economic cartels—in place. Authoritarian governments rule over a largely passive or, perhaps more correctly, pacified populace, but they do not try to reshape those masses into instruments of radical social change. True fascist movements on the other hand attempt to energize and mobilize the masses in an effort to restructure and refashion society along specific ideological lines. The historian Robert O. Paxton (2004) has argued, and this is sure to be contested, that Franco's Spain, Salazar's Portugal, and Peron's Argentina, while ruling in an authoritarian manner, never envisioned nor attempted to create a new order, a world radically transformed through “redemptive violence.”

The Emergence of Fascism

The word “fascism” is rooted in the Latin *fascis* (“bundle,”) and the *fascēs*, an ax girdled by a bundle of rods that was carried before the magistrates in ancient Rome. The *fascēs* symbolized both unity and authority as achieved through the absolute rule of law. Benito Mussolini (1883–1945), an Italian socialist turned rabid nationalist by World War I, employed the term *fascismo* to express the sentiments of those who united in support for the Italian war effort and subsequently rejected those socialists and communists who, as internationalists, opposed it. Mussolini eventually formed a movement he termed the *Fasci di Combattimento* (Combat Group), to promote what was variously termed national syndicalism, national corporatism, or national socialism (a term that was bandied about Europe after World War I and used

This 1942 broadside shows three unsigned cartoons depicting ideological enemies of Benito Juárez, the nineteenth-century, five-term president who symbolized Mexican democracy; the text comments on ideals threatened by fascist elements in Mexico. *Artistas Libres de Mexico, Mexico City, 22 Marzo 1942.*

most notably by the German National Socialist or Nazi movement).

This "Third Way," as many supporters called the path of fascism, hoped to combine the passionate nationalism of traditional conservative elites (while at the same time rejecting aristocratic hierarchies in favor of a meritocracy founded on strong male leadership) with a socialism based not on class conflict, but on a cooperation of classes that would result not only in more equitable economic distribution, but in a more unified and powerful nation. The fascists hoped to create a new order, a transformed world that eliminated or at least ameliorated what they saw as negative aspects of modernity, such as capitalism and its attendant consumerism (understood as

wanton materialism), feminism (understood as an unnatural rejection of male supremacy), liberalism, and especially communism (understood as leading to an equally unnatural social leveling that allowed mediocrity to rise to the heights of power). This rejection of the "corrupting" influences of modernity led many Christian clerics to support various fascist movements around Europe (Feldman 2008). Since Mussolini's fascist movement was the first to achieve power and notoriety, the term fascism was quickly picked up by, or attached to, a number of similarly focused groups that emerged in the following decades throughout Europe, Latin America, Asia, Africa, and elsewhere.

Fascism as a Response to Modernization

The fascist rejection of prominent aspects of the modern world led some contemporaries and later scholars to see the movement as a reactionary rejection of modernity. Consequently opponents argued that fascism was an antimodern triumph of barbarity and irrationality—little more than nihilism empowered. But such a view is at best only partially accurate. A closer look at the interrelationship of fascism, modernization, and modernity is warranted.

Modernization is a process of rapid change rooted originally in the Industrial Revolution. The many changes wrought by industrialization radically altered traditional political, social, and economic structures and patterns of behavior. For instance, urbanization and the resultant migrations of people from rural areas to cities changed patterns of work, which in turned changed traditional familial and gender relationships, often experienced against a backdrop of shockingly new cultural forms in art, music, and literature. All this change, often occurring rapidly, generated a strikingly new culture that was a tenuous fusion of remaining elements of the traditional preindustrial culture and the new industrial world. It is this fused culture that we call modernity.

While modernization originally began in western Europe and the United States, the process quickly

began occurring in other parts of the world, first generated by Western imperialism, but later through indigenous efforts to modernize traditional political, social, and especially economic structures. Although modernization as a process is fairly uniform, the traditional cultures around the world that have been and are being affected are myriad. Therefore the modernity that results from the fusion of traditional preindustrial and industrial societies will be different each place modernization occurs. It is best then to speak of multiple and culturally varied expressions of modernity.

Fascism is most likely to arise in those places where the delicate negotiation between traditional and modern elements breaks down. In other words, fascism tends to emerge where modernity fails. The fascist rejection of elements of modernity, such as unchecked capitalism, liberalism, communism, and feminism, is more than simply antimodernism. Indeed most fascist movements embraced modern technology, such as radio, film, amplified sound, planes, and automobiles, as a means not simply to return the nation to its preindustrial culture, but to transform the new industrial world into something different. Fascists are not simply rejecting modernity, but attempting to create an alternate modernity (Griffin 2007).

Core Myths and Mobilizing Passions

Recent scholarship has taken a closer look at how the fascists interpreted the modernity they lived in, and how they envisioned the alternate modernity they hoped to create. The historian Roger Griffin (in *The Nature of Facism* 1993) and Paxton (2004), while disagreeing on many issues, both see important similarities in what they term respectively the core myths or mobilizing passions of the fascists. These central beliefs impelled the creation of the movements, shaped their development, and mobilized the masses that supported them.

The fascists believed that the modernity they lived in was decadent and degenerate. It was in a state of extreme crisis approaching apocalyptic proportions.

The nation, in fact the world, had reached a historic turning point, a time of apocalypse or salvation. The degenerative forces of modernization were often associated with what was variously termed Westernization or Americanization (meaning materialism or consumerism, female liberation, indecent art and music) and, in the case of Nazism, localized primarily in the imaginary machinations of the Jews. Cleansing the nation of those degenerating forces would lead to a rebirth of the nation and indeed, a regeneration of the world. The fascists saw themselves as a chosen elite under the command of a leader to whom they were attached with near messianic devotion (Kallis 2008). The leader and the led believed they had a mission to purify modernity, often through violence that was conceived as a redemptive. The nation resurrected and the world saved, the fascists hoped to usher in a new age, an alternate modernity that would combine desired aspects of an often mythologized glorious preindustrial culture with elements of the industrial world that were desired (such as the energy of the accelerated pace of urban life, which, if properly channeled, could transform the industrial masses from a chaotic horde into a unified, mobilized, and redirected community). The fascist conception of rebirth therefore is as future-oriented as it is backward-looking, combining the myth of the golden age with the myth of the emerging new age.

The Italian scholar Emilio Gentile (1996) called this use of myth a “sacralization of politics,” and argues that fascism is a form of political religion. However, it can be counterargued that fascism also includes a secularization of millennialism, as the core myth detailed above is clearly apocalyptic, millennial, and messianic. This is certainly the case with Nazism, a movement that was interpreted by its followers as being a spiritual response to a spiritual crisis of apocalyptic proportions. They believed their leader was sent by God to save not only Germany, but also the world (Redles 2005). Millennialism itself is but one possible response to rapid and radical change brought on by any number of converging catalysts, the forces of modernization being but one. Seen in this light

Perhaps America will one day go fascist democratically, by popular vote.

• William L. Shirer (1904–1993)

fascism may be a modern variant of millennialism, secularized in some cases, still sacred in others. Most likely it is a fusion of both the secular and the sacred, since fascism, like the modernity it responds to, is a hybridized phenomenon.

The Future of Fascism

When communism fell in the late 1980s, many Eastern European countries were challenged by sudden entry into free market economies, loss of welfare safety nets, and the rapid influx of Western and especially American culture. All this rapid change was accompanied by an increase in organized crime and a proliferation of prostitution and even sexual slavery. Not surprisingly, the 1990s and the dawn of the new century have seen the appearance of fascist or at least neofascist movements in former Soviet bloc countries like Germany, Poland, Hungary, and Slovenia and in the Balkans, as well as in the Soviet successor states Russia and Ukraine (Fenner 2004).

Western Europe, however, has not been immune from neofascist or populist movements, as socialist welfare systems struggle under an aging population and increased use of immigrant labor that has generated intense resentment amongst indigenous workforces. Moreover, one can argue that the shift from industrial to postindustrial economies creates a new variation of modernity, as societies create a new cultural fusion of former industrial society with the emerging new postindustrial culture. Where this new modernity struggles to develop, fascist-oriented movements may continue to arise.

The United States, while it has never seen a single fascist movement with broad populace support, has had numerous right-wing movements that overlapped with fascism in both ideology and practice, such as the Aryan Nations of Christ and even the Ku Klux Klan (Berlet 2000). Many of these movements have had a strong evangelical Christian core, interpreting modern America as culturally decadent and morally bankrupt, and further believing that the country is both the seat of the coming New Jerusalem and a battleground with those liberal forces they believe are

threatening apocalypse. The millennial core shared with fascism is clearly there, as is the rejection of modernity and the desire to create an alternate Christian modernity, a new America cleansed of ungodly materialism, liberalism, and Hollywood degeneracy. Most scholars believe, however, that a profound political crisis, unlike any seen in U.S. history, would be necessary to take such Christian fascism from the margins to the mainstream.

The failed modernity that has occurred in much of the Middle East (western Asia) and Indonesia, and the subsequent rise of radical Islamic militancy, has led some to interpret events like the Iranian revolution of 1979, the Taliban takeover in Afghanistan, and the rise of the al-Qaeda terrorist organization as forms of Islamic fascism. Contrary to traditional fascist movements, Islamic fascists hope to resurrect, not a strong, unified nation, but a purified multinational caliphate. However, unlike actual historical caliphates, which were often models of pluralism and religious tolerance, the new Islamic fascists hope to cleanse their countries of all degenerate influences. Like earlier fascists, the degenerate forces of modernity are usually associated with the West in general, the United States in particular, and quite often projected upon the Jews of Israel. The Islamic fascists also share with other fascists an overly militarized culture that favors male dominance as being both natural and divinely inspired. The emphasis on the control or protection of women is rooted less in Islamic religion than it is in a rejection of the so-called corrupting influences of modernity. Women therefore become pawns in a game between an imagined coming purified caliphate and the corrupt modern world. Much more research, however, needs to be done to ascertain if movements such as those that arose in Afghanistan or Iran are truly a form of clerical fascism, or simply religious tyrannies that share with fascism a rejection of modernity and employ a similar symbolic vocabulary.

If we see in fascism one possible response to the rapid and radical change brought on by modernization, and if we further see modernization as an ongoing and never-ending process, then we can expect

fascist movements to continue to arise. Fascism then, unfortunately, may still have a future.

The term *feminism* was coined in the late nineteenth century, nearly a hundred years after Mary Wollstonecraft's pioneering advocacy of education for girls in Europe. It has come to encompass a broad range of political, cultural, and intellectual movements. An underlying vision of a more just society, where males and females have equal or equivalent opportunities for work, service, and personal development, connects feminist individuals and organizations worldwide.

In 1913, Rebecca West (1892–1983) famously wrote: “people call me a feminist whenever I express sentiments that differentiate me from a doormat or a prostitute.” Even today, it is sometimes easier to determine who the feminists are by watching their opponents than it is to describe a version of feminism that would fit all the common kinds of feminist activities. In part this is because the word *feminism* was first used in the late nineteenth century, and thus postdates many of the earliest activities and thinkers it is used to describe. As used today, *feminism* is a broad term encompassing political, cultural, and intellectual movements as well as the worldviews of individuals.

Since the early nineteenth century feminist activists in many parts of the world have sought to provide women with legal recognition, human rights, protection within the family, suffrage, maternity leave, day care, sexual freedom, equal opportunity to employment, access to health care, and dress reform, among many other issues. Some feminists turn their commitment to women's rights into full-time employment; some work as volunteers; some support political

parties, charities, nonprofits, and/or nongovernmental organizations they perceive as having a pro-woman agenda; and some simply try to act out of feminist principles in their daily lives. Individuals and organizations that self-identify as feminist have a wide variety of outlooks, histories, and agendas, with the result that there is often considerable disagreement among them. Sex work and religious obligations are among the most contentious issues of the current day, for example, while universal male suffrage was the hot-button topic of nineteenth and early twentieth century First-Wave feminism.

What connects feminists is an underlying vision of a more just society, where males and females have equal or equivalent opportunities for work, service, and personal development, and where the government provides men and women with equal or equivalent protection and responsibility. Contemporary organizations that self-identify as feminist almost universally voice and may provide support for movements seeking ethnic, racial, and class equality. Many also support the legal equality of lesbians and homosexuals, including the right to form legally recognized families. Individuals who self-identify as feminist are more divided. In any case, assigning women legal rights, access to education, sexual and financial independence, and responsibilities equal to those of men required and continues to require vast changes in the structure of families, production, government, and social interaction.

History

“First Wave” feminism began as a self-conscious organized political movement in 1848 in Seneca Falls,

This photo, labeled “Colliery lasses marching during the British coal strike,” was taken between 1910 and 1915. George Grantham Bain Collection, Library of Congress.

New York, where Elizabeth Cady Stanton (1815–1902), Lucretia Mott (1793–1880), and Susan B. Anthony (1820–1906) held the world’s first Women’s Rights Convention. The leaders of what would become the Women’s Rights movement published a Declaration of Sentiments modeled on the United States’ Declaration of Independence, saying that men and women were created equal under the laws of nature and of God, and that women should “have immediate admission to all the rights and privileges which belong to them as citizens of the United States.” Using the political language of Thomas Hobbes, John Locke, and Thomas Jefferson, they demanded legal and political rights equal to male citizens. Thus, although the first feminist body called itself the National Women Suffrage Organization, members actually campaigned for a variety of legal remedies. For instance, their first political victories increased married and widowed women’s ability to own property and make contracts.

Although U.S. women probably had more experience as political activists than women in other countries, women in the European and Latin American world had also been voicing feminist sentiments and supporting political movements prior to 1848. U.S. activists corresponded and worked with individuals and organizations in many other areas of the world, and newspapers around the world wrote stories and editorials about the Women’s Rights Convention and

the NWSA. The first college (Oberlin College graduated its first women students in 1841) and many of the earliest colleges to grant degrees to women students were in the United States, and the arrival of women from all parts of the globe helped disperse the political language and strategies of the women’s rights movement. Within a very few years there were organized feminists in western and eastern Europe, Brazil, and Mexico, and by the end of the nineteenth century there were feminist movements and organizations in India, China, North Africa, and much of the rest of Latin America.

Feminists were particularly influenced by Mary Wollstonecraft (1759–1797), whose *Vindication of the Rights of Women* had asserted that women deserved to have educations on par with men, as well as greater legal equality. It was Wollstonecraft’s realization that social inequalities were not simply natural, but instead at least partly created by cultural norms. Women in European society, she said, were indeed less capable than men of acting wisely and effectively to support themselves, their families, and potential responsibilities as citizens. She perceived this as being the inevitable result of weak education, however, rather than of any mental or biological incapacity of girls and women. A girl educated to support herself and to actively engage in public life would grow into a woman capable of doing so, and so the education of girls lay at the heart of Wollstonecraft’s vision for

Female students in the Department of Domestic Science—Chemistry, (1893). Illustration by Louis Loeb, engraved by C. Schwarzbürger for *Century Magazine*.

achieving women's rights. Early feminists the world over considered Wollstonecraft's ideas indispensable; the NWSA sponsored its widespread distribution, and a translation of the *Vindication* was the first book actually published by a Brazilian woman.

The campaign for women's suffrage was considered the most radical branch of the women's rights movement, and opponents described suffragists as anti-male and irrational. On the other hand, campaigns for girls' education met with less resistance. There were several reasons for this. First, as industrial economies progressed, more and more women had to undertake wage labor outside the home, making some form of childcare a necessity. Schools provided a partial solution to that problem. Second, nineteenth-century gender ideology depicted mothers and wives as housewives whose most important task was building their children's characters and educating them for citizenship in the modern world. To do this, women required an education.

Third, the image of the appropriately educated and independent modern woman was an important piece of imperialist and anticolonial ideology. The leaders of colonizing powers, of independent states resisting colonialism, and colonized elites all believed that women's dress, activities, and public presence were critical indicators of modernity and national health. Therefore, in some countries elite men made the earliest attempts

at feminist social change and created the first institutions that supported it. Muhammad Ali (1769–1849), a pasha of Egypt, supported education for girls and midwives in Egypt; affluent men organized the first Chinese movements opposing foot binding and female slavery, and tried to persuade their families to educate daughters and find educated wives for their sons. Finally, women's organizations and individual women all over the world worked hard to promote the idea that women's education was an indispensable part of modernity; in many places, the first professional jobs women held were as schoolteachers. Whether they were in India or Indonesia, these small numbers of educated unmarried women started a surprisingly large number of publications and organizations devoted to various aspects of women's interests. They made up the backbone of women's organizations in general, not just the women's rights movement. Less radical feminists organized for goals like child welfare, protection of minor girls from prostitution, support for widows, and the cure and prevention of alcoholism (so that men would not spend all of a family's income on drink or beat family members while drunk).

Not all women's organizations and movements involved themselves in overt political activism on behalf of women's legal rights, in part because there were relatively few countries where open political protest was legal, and even fewer where most

Changing role patterns: mom reads the newspaper while dad prepares dinner and keeps an eye on the family. Haarlem, The Netherlands, 1982.

adult men had the right to political participation as voting citizens. Radical women in more repressive societies like Russia and India tended to align themselves with revolutionary or independence movements as much as with women's movements. European activist women often became socialists, and in the various colonies they frequently joined women's auxiliaries of nationalist independence movements. Feminists in these movements saw women's rights as being dependent on (and naturally flowing from) political freedom for their countries as a whole.

In the 1950s, feminist movements accelerated as international independence and civil rights movements began to bear fruits in the form of decolonization and greater recognition of the human rights of minorities. Originating in countries where women already held the franchise, this Second Wave of feminism continued the work toward equal rights and the protection of women and girls so important to the First Wave. Also often called the Women's Liberation movement, the Second Wave has emphasized the importance of changing gender ideology and gender expectations feminists perceived as limiting and coercive for both sexes. Some feminists refer to the current period as a "Third Wave" of feminism, but aside from

the changing generation of leadership there seems to be no clear agreement as to how the Third Wave differs from the first.

Opposition

Feminist movements typically encounter considerable opposition, in part because even small feminist changes create large-scale social and political change. It is not possible, for instance, to simply grant women the vote and go on doing business as usual. In countries with large Roman Catholic populations, for instance, Liberal parties typically feared granting women the franchise because women supported the church more than men. When widows retain a greater share of their husbands' properties they were able to use those funds to do things like endow public buildings and charities, support political candidates, build private women's colleges, live alone, support a (male or female) lover, or any other legal activity they pleased. Laws raising the age of sexual consent or of legal marriage cause girls to marry later, have fewer children, and generally be more capable of opposing the wishes of their husbands or in-laws if they so choose. Women with access to contraception—and there continue to be many women who do not have such access—are able to choose for or against childbearing and control the number of children they have. Implementing feminist reform inevitably transforms the lives of boys and men and forces reexamination of their roles in society. Moreover, it is not only husbands but also parents, including mothers and mothers-in-law, who experience a loss of authority. Grandmothers, mothers, and mothers-in-law often hold great authority in highly male-dominated societies, so that basic feminist reforms providing greater freedom for girls and women can have the impact of removing younger women from the authority of older women. Feminism is therefore criticized as being incompatible with traditional family values.

Another current critique of feminism has been that it is a movement of middle class and Western women. For much of the history of feminism, middle class

Remember, Ginger Rogers did everything Fred Astaire did, but she did it backwards and in high heels. • Faith Whittlesey (b. 1939)

and/or educated women have made up the backbone of the movement, while the financial and social backing of wealthy women has often been critical to the survival of particular organizations. This is, however, also true of most organizations dedicated to political and/or charitable activity. Perceptions of feminism as a Western, imperialist project derive from the connections so often drawn between modernization, civilization, and women's status during the colonial period. It therefore is still the case that many organizations and individuals working on agendas that feminists would support nevertheless refuse to self-identify as feminist. This is similar to the way some women's organizations of the nineteenth century worked for "women's issues" such as education, sanitation, and other forms of social welfare while avoiding official support for suffrage.

Festivals

Peoples throughout history have engaged in festivals—joyful, playful, and celebratory occasions, usually occurring at regular intervals—that often have a religious or cultural significance. Festivals can often provide an atmosphere conducive to achieving a number of societal goals, including the creation, preservation, and encouragement of societal unity.

Festivals occur in all societies and range from performances associated with major religious traditions to localized ritual entertainments and celebrations. Festivals share a sense of license and play. They allow participants to express meaning on a number of levels. Representative meaning is the first: people attempt to convey the essence of what the festival portrays. Next is an iconographic level: the thing represented, for example, is not just a bear or a woman but rather a sacred figure, a bear deity or the Virgin Mary. The next level is interpretive or metaphoric, allowing symbols to address issues in the wider society, perhaps conflict or tension.

Festivals perform a number of functions in society. The anthropologist Frank E. Manning (1983) placed festivals in the category of *celebration*. Festivals and other forms of celebration give power to those people who normally do not exercise it, providing an opportunity for people to comment on the political powers in society, for example, and to pretend or suggest that things may be other than they seem. Finally, the festival performance itself has a social and cultural context. Festivals have a cultural function; that is, they extend beyond themselves to shape identities and communities.

Often that unity must be maintained in the midst of diversity, whether of diverse people within society

or of competing political and economic interests. An example from the United States illustrates this point. Because of the massive influx of immigrants into the United States after World War I, the government published a manual of suggestions to promote U.S. national solidarity and patriotism. Basically, the manual suggested performances of festival activities to promote “Americanization” of immigrants. One suggestion was to have immigrant children climb into a giant shoe that was wheeled onto a stage. Then the shoe would be unveiled as “America.” Children wearing clothing symbolic of their home countries would emerge from the shoe, take off their symbolic caps and kerchiefs, and appear transformed as “Americans.”

The element of reversal—immigrant children transformed into U.S. citizens—is present in most festivals. Newfoundland mummers (performers in a pantomime), for example, perform for what most people would term simply “fun.” Certainly the riotous fun of their performance and its accompaniment provide a good time. But the good time allows even the most conservative members of the community to break the rules. It is a time of license, of what anthropologists refer to as “ritual rebellion” or “ritual of inversion.”

Festivals Celebrating Unity

Festivals embody the world of play, imagination, and creativity. Occasions of festival or carnivalesque license tend to reaffirm unity. They not only provide breathing room, but also point to problems within society. By holding these problems up to ridicule, festivals enable people to laugh and prod those who have the power to fix the problems.

National Powwow, 2007. Traditional Native American dances from past centuries have evolved to include contemporary aspects. Photo by Cynthia Frankenburg for the Smithsonian Institution.

The Palio festival of Sienna, Italy, is an example. The Palio is both a parade and a horse race. It is also a religious and political event. The people of Sienna use this festival to seek the regeneration of their city. The competitions that comprise the Palio—parade competition, horse races, political and religious maneuvering—are on a lower level of urban life. However, a higher level of urban life keeps these competitions within limits and works toward their resolution, leading to a restoration of unity.

Festivals of the dead are also common throughout the world as affirmations of life and unity. They frequently take place a year or more after the death of a person and involve villagers, relatives, and age mates of the deceased. The cost and preparation are enormous. The festivals feature a great deal of eating, dancing, singing, and celebrating. Revelers sing songs and tell stories that recall the events of the deceased's life. Objects associated with the deceased are displayed and may be given away. The festivals serve to renew ties within the

community, bringing together old friends, relatives, and others.

The Iroquois of western New York showed the incorporating purpose of festivals quite clearly. Among the Iroquois, prisoners were never exchanged. If the Iroquois did not kill a prisoner, they adopted him, which meant that the prisoner had to change his identity. At the next religious festival elders pronounced the prisoner's new individual name, tribe, and family to the community. The opposition between the old identity and new identity was ended in the religious festival, as was the opposition between the former prisoner and his new nation.

The Ox Dance (Boi-Bumbá) festival in Parintins, Amazonas, Brazil, is performed the last three days of June. It has become the largest and most magnificent folk festival in northern Brazil. It, too, supports the idea of seeking unity in opposition. On the one hand, it asserts *caboclo* (mestizo—a person of mixed European and Native American ancestry) identity through use of cultural and ritual themes. On the other hand,

it asserts that identity in a positive fashion as part of being Brazilian.

Anthropologists have long viewed U.S. town festivals as equivalent to public ritual in traditional society. Again the theme of a public ritual's ability to reflect community values and contemporary relations is present. For example, the U.S. West celebrates a number of festivals similar to the Frontier Days of Cheyenne, Wyoming. These festivals include competitive events that are resolved in unity, including parades, rodeos, carnivals, bazaars, livestock shows, and musical performances. These festivals unite people in a common heritage while releasing tensions and fostering pride and unity.

New Year Festivals

Many societies, most famously the Chinese, stage New Year festivals. The Chinese observe a lunar calendar; thus, their New Year falls on a different date than that of the Western calendar. A number of rituals are associated with the festival, beginning about a month before the new year starts. People begin to purchase presents to give away, special food, clothing, and decorations. The festival preparation includes a massive house cleaning, including a thorough broom cleaning to sweep away bad luck. People also repaint doors and windows, usually in the lucky color red. The Chinese then decorate doors and windows with paper decorations representing happiness, wealth, and longevity. For many people the highlight of the festival takes place on New Year's Eve. In fact, people pay greater attention to details of food, customs, and rituals on the eve of a new year than on the first day. Food such as seafood and dumplings represent good wishes. Other foods also have symbolic value: prawns represent liveliness and happiness, and fish salad is said to lead to good luck and prosperity. People usually wear red to ward off bad spirits and avoid black and white clothing, which represents sorrow and mourning. After an evening spent in family celebration, people watch midnight fireworks.

On New Year's Day married people give children and unmarried adults money wrapped in red

envelopes. Families go visiting, wishing people happiness, indicating their willingness to forgive and forget offenses and asking others to do so in return. The festival seeks to restore peace and harmony in the community.

African Festivals

Throughout history African festivals have provided people with a means for making social and political commentary, even a structured form for rebelling and changing governing policy. Into the present day these festivals have the same social functions—to keep society open and to allow for commentary on mores, customs, and political organization. African festivals fit well within the ludic framework. The song, dance, and costumes are entertaining, but their playfulness adds to the possible subversion of commonly accepted definitions of reality. These festivals both reflect and aid changes found in society, helping to ensure that changes appear to fit well within the cultural traditions of the group.

The names of these festivals may change over time, but their purpose remains familiar. During the transformation of Hausa society that resulted from colonialism, for example, the *Wasan kara-kara* ceremony underwent changes, including a change in name. During colonialism, white administrators and other members of colonial society became the butt of humor. The Hausa introduced “white masquerades” because no white man would portray another white man during an African masquerade in a derogatory manner. Consequently, Hausa masqueraders put on a white face to mimic the white colonial administrators and to satirize those with political power so that they could mend their ways.

In other parts of West Africa the Poro and Sande/Bundu associations used festivals to maintain societal order. The Poro and Sande used spirits to aid in their occupations. Similarly, the Egungun masquerade societies of Yoruba in southwestern Nigeria used spirits to establish and control social order.

Dance and Festival

Generally in Africa, a festival is not a festival without masquerade dancers. These dancers are members of religious societies. Four kinds of masqueraders exist. Each kind has a particular role: (1) to represent gods or spirits of nature, (2) to embody ancestral spirits, (3) to soothe the gods through dance, and (4) to entertain.

Different kinds of masks also exist. The animal mask is common. It has different styles and represents different forms of animals. Some masks are small and graceful, whereas others are large and adorned with swaying raffia (fiber of the raffia palm). Dancers adapt their style of dancing to fit the kind and size of the mask they wear. For example, the Ikpelweme ancestral masqueraders of the Afemai people of Bendel State, Nigeria, wear costumes that are skin tight and deeply colored. They also wear masks and headpieces made of embroidered cloth. These dancers are able to execute rapid dance movements. The Yoruba Egungun ancestral masqueraders, on the other hand, wear carved headpieces and loosely flowing robes. The masks are quite heavy and prohibit rapid dance movements.

Entertainers everywhere have evolved from ritual societies. They generally are hired to perform for a fee. They might perform, for instance, at a ritual festival, but they also might perform at a private party. They are generally obliged to sacrifice to an ancestral spirit. After the sacrifice they perform acrobatic dances, tinged with magical quick changes. They also ridicule strangers, especially any Europeans in their view.

Dance in Africa is joined with music and song and defines the function of individuals and groups within the community. In Tanzania the ritualist who circumcises a child may also perform a dance. The ruler in a complex African society must perform a formal ritual dance to state his authority. Among the Yoruba of Nigeria the ruler leads masqueraders through town while dancing within a carriage. His wives dance, as do subordinate chiefs. Then other members of society perform dances appropriate to their ranks—hunters, palace chiefs, women market chiefs, and so on until all have paid homage through dance.

Secret Societies and Festivals

The Poro and Sande associations of West Africa are generally presented as preeminent models of secret societies. However, other secret societies exist in Africa. The Egungun masquerade societies of the Awori and Egbado territories of southwestern Nigeria, for example, are of fundamental importance in the life of the people. The masqueraders play a basic role in the political life of the community, as they have for many centuries.

The Ogun festival is supposed to be a celebration of Ogun, the god of iron. However, the Yoruba masqueraders, in defiance of many born-again Yoruba Christians and the traditional ruler, use the festival to celebrate the prowess of the Yoruba people. The young men who take part in the festival assert their right to control Yoruba political life and help define the meaning of culture.

Thus, the masqueraders present another example of old forms being adapted to new circumstances, in this case, the changing political scene and the struggle between older and newer definitions of political power and culture.

Masks and Festivals

Essentially three types of masks exist. One type is worn for theatrical effect. These masks impress instantly by their size. They exaggerate reality by being larger than the wearer's body, for instance. Other masks conceal one's human individuality. The person wearing such a mask takes on another identity, usually that of a more powerful person. Finally, some masks embody power, the ancestors. Because they are so powerful, such masks are not worn. Rather, masqueraders drag these masks behind them.

People usually wear masks at religious festivals. Such festivals feature dances and music. The dances tell a story; usually the story refers to good or bad ghosts. Good ghosts aid the harvest and chase the bad ghosts who try to spoil it.

Depending on whether the main crop is grain or yam, people stage either a grain or a yam festival. A yam festival generally is held at the end of the rainy season in early August. In Nigeria and Ghana people

offer yams first to the gods and ancestors to give thanks. In Ghana people also celebrate the Homowo festival. It is a traditional harvest festival among the Ga people. The word *homowo* translates as “hooting at hunger.” It comes from the mythical origin of the Ga and refers to their migration into Ghana. On that migration they were on the edge of starvation. However, through their mutual aid, they survived. When they succeeded at producing a surplus they had their first Homowo festival. The festival includes a masquerade, with people representing various royal figures.

Characteristics of Masquerades

Each masquerade has a number of statuses within its formal structure. Each group has a particular role to play in the overall cult. The cult helps keep the political process going. Within the lineage organization of Yoruba society each family group has its own particular function. Interestingly, the Yoruba use the masquerade as the Hausa use the Wasan, namely to control the political situation.

Essentially, the masquerade is a ritual that reflects the surrounding political structure. Behind the masks of uniformity, many interests compete. Masks represent these interests. Members of different groups negotiate which groups will control various aspects of the festival and, consequently, political life. Masks identify individuals as members of competing groups who ultimately work to control political decisions.

In Ikole in southern Nigeria the official and most important festival is the Ogun festival. The Odun Egun, a biannual masquerade festival in late spring, also is important. It lasts seventeen days and features masquerades that reflect the shift in power from the old to the young. The young masquerades get to be performed more frequently than the old ones as power shifts from one generation to another.

The fact that festivals are rituals in themselves and contain a series of rituals also allows them to mask change under the rubric (rule) of continuity. Festivals are frequently centers of competition,

and the competition is incorporated within the formal structure of the festivals. By observing the same festival over time people see these changes. Festivals, therefore, both encapsulate much of the cultural history of the group and provide a means for change.

Feudalism

Feudalism is a much-contested term in world history. Scholars most often use it to describe certain political (and sometimes economic) systems in the preindustrial world, but they have not agreed on the characteristics that define a system as feudal. As a term that is paradoxically both too vague and too precise, an increasing number of historians consider it best avoided except in very restricted historical fields of study.

Feudalism has most often been used to describe the political fragmentation and arrangements for raising military manpower that allegedly arose in Europe around the ninth century and theoretically persisted for many centuries thereafter. Most historians of medieval Europe, however—especially military historians, for whom the term should ostensibly be most germane—now consider it a misleading term that does more to obscure than to illuminate our view of the past.

History of the Term

Though based on the medieval word *feudum* (Latin for *fief*), reformers in the eighteenth century coined the word *feudalism* to describe (unfavorably) the system of rights and privileges enjoyed by the French aristocracy, especially with regard to their landholdings and their peasant tenants. This broad socioeconomic meaning was taken up and extended by Marxist historians, for whom the “feudal mode of production” succeeded the classical mode and preceded the capitalist mode. For military historians, this definition has always been far too broad. Indeed, if a privileged landholding class and a subject peasantry constitutes feudalism, then most civilizations before

the industrial revolution were feudal, and the term loses its analytic usefulness. In this sense *feudalism* also becomes conflated with *manorialism* (the organization of rural production into manors held by lords and worked by subject peasant labor).

Feudalism and Military History

Military historians have usually taken a more restricted view of feudalism. For them, it is the system of raising troops in which a lord grants a fief—typically a piece of land—to a vassal (Latin *vassus*). In return, the vassal gave the lord a defined and limited term of military service, usually forty days a year and usually as a knight—a fully armed and armored horseman. Sometimes the lord provided the armor and weapons, but often the vassal provided his own. The fief was the payment for service and was also known as “the knight’s fee.” Feudalism in this sense has often been taken as the sign of a weak central authority with limited cash resources, forced to substitute land for cash and to devolve local power to its aristocracy; in fact *feudal* is often used simply as (somewhat misleading) shorthand for “decentralized polity dominated by a powerful warrior aristocratic class.” But not all decentralized polities raised troops using land-for-service arrangements, nor were all polities that did utilize such arrangements weak, poor, or decentralized.

Indeed, these arrangements did not even characterize what has been regarded as the prototypical feudal society of northwestern Europe from the ninth to the twelfth centuries. Recent research has traced modern conceptions of feudal service to the terms and definitions of the *Libri Feudorum*, an Italian legal handbook written in the twelfth and thirteenth centuries. Its

The feudal Castle at Himeji, Japan, built in the fourteenth century and renovated in the seventeenth, is famous for the complex maze of paths leading to the main keep. New York Public Library.

academic view of fiefs and vassals became the basis for the sixteenth-century interpretations of feudal institutions that have held sway ever since. However, this picture of feudal service and the legalistic hierarchy of landholding rights associated with it does not fit the medieval evidence. *Feudum* and *vassus* were vague and mutable terms, and European military systems from the ninth to the fourteenth centuries were far more varied, flexible, and rational than conventional interpretations have supposed.

Restricted service in return for granted land was inherently limited as a basis for a military force—leaders always needed soldiers available for more than forty days a year, at the least—and this system has been overrated as the source of medieval European armies. Soldiers did serve for land, but often they were “household knights”—young men who lived with their lord and served him in military and non-military capacities—who were rewarded for long service with land of their own and served in anticipation of this reward. Even service for land already granted was far less defined and restricted than the traditional “forty days a year” formula implies. “Feudal” service (unpaid service by the vassals of a lord) worked best on an informal basis: a lord in need of armed support in his local disputes and in serving his own lord (if he had one) called together the young men who were his friends, relatives, hunting and drinking companions, and social dependents, and they campaigned together, sharing the risks and rewards of warfare.

Social cohesion in the lord’s military household (Latin *familia*) translated into military cohesion, and constant hunting and fighting together imparted small-unit skills. Restrictive and legalistic terms of service played almost no role in such arrangements.

There are also problems, however, with defining feudalism more generally as a landed support system for unpaid military service. First, individuals and groups also served for pay in medieval Europe from an early date, wherever economic conditions made it possible and even when they owed “feudal” service. Paid service became increasingly common in the period after 1050. Second, in a global context there have been many forms of “soldiers’ lands” in different times and places, in combination with paid and unpaid service. Some involved the granting, not of possession of a particular piece of land, but of income rights over the land. Income rights were often, in fact, granted from several different pieces of land. Arrangements such as these, which entailed no direct link between the military manpower supported by landed income and the peasant manpower working the lands, differ fundamentally in type from arrangements in which the warrior who was granted the land assumed legal control over the peasant population and managerial control over the output of the estate. Indeed, in some cases the military manpower supported by designated “soldiers’ lands” was not in a position of social and political dominance—it was not, in short, a warrior aristocracy, but instead

Mercenaries and auxiliaries are useless and dangerous. • Niccolò Machiavelli

constituted a sort of militia. Arrangements such as these also differ in type from those that were set up for a dominant warrior elite.

Therefore, to call all land-for-service systems of supporting military manpower “feudal” is to arrive again at an overly broad definition, akin to the problem of the Marxist definition of feudalism, which makes no useful distinctions between systems and their individual characteristics. To try to distinguish some such systems as “feudal” while excluding others has inevitably involved privileging the characteristics of the European model in order to arrive at criteria for inclusion, for no reason than that it was studied (and called *feudal*) first—a pernicious instance of Eurocentrism. Military historians are thus increasingly avoiding the term, and are turning instead to functional descriptions of the world’s (and Europe’s) varied military systems of landed support, militia service, and the social hierarchies that accompanied them.

Feudalism and Legal History

Legal historians of high medieval Europe, on the other hand, can more confidently lay claim to the term *feudal* in their sphere of inquiry: in the more settled European conditions of the twelfth century and later, the informal arrangements of an earlier age tended to crystallize into formal legal arrangements with defined terms of service and inheritance rights on the part of the vassal. This process marked the decline of “feudalism” as a viable military system, but the rise of feudalism as a fundamental legal system. Indeed, the lord-vassal tie of landholding became crucial as one of two key bonds (along with marriage, which it resembled) among the European aristocracy. The twelfth-century English system of fief law became the basis of most later English estate law and thence of modern American property law.

Feudal property law has a definite history, but perhaps because that history is so clearly tied to the specific times, places, and legal systems that generated it, legal historians—whose stock-in-trade tends to be particulars rather than generalities—have not been tempted to see feudal property law as a transcultural

historical phenomenon. The mistake for nonlegal historians is to read the legal history of high and late medieval Europe back into the political, military, and economic spheres of early medieval Europe, and then to extend that misreading to other areas of the world in the search for a general type of society.

Feudalism and Comparative History

An example of such a historical misreading is provided by the study of “feudalism” in Japan between the twelfth and sixteenth centuries. The dominance in Japan from Kamakura times of a rural warrior aristocracy in the context of somewhat weak central government has long invited comparison of Japan with medieval Europe, where similar conditions prevailed. Such comparisons have almost always been cast in terms of feudalism: since the traditional model of feudalism arose from the study of western Europe, looking for feudalism elsewhere risks shoehorning non-European histories into a European mold. This raises the possibility of misreading the evidence to find anticipated feudal characteristics, or, if a different trajectory is seen, of explaining what went “wrong” in the non-European case.

This tendency has afflicted Western views of Sengoku Japan, the period during the sixteenth century when Japan was divided into warring domains headed by daimyos, or local lords. The feudal model has led many historians to see the Sengoku age as the epitome of feudal breakdown and anarchy. Daimyo domains are equated with the small castellanies and lordships of northern France, the feudal kingdom (French and Japanese) taken as the unit of comparison because of the prominence of weak central authority in the feudal model. By emphasizing the division of the larger political unit, however, this view obscures important forces of unity and political cohesion that were developing within the daimyo domains during this period. Without the feudal preconception, daimyo domains appear more readily as independent polities within a Japan that is more akin to Europe as a whole than to any one kingdom within Europe.

At a lower level of the feudal model, the European norm has inspired numerous comparisons of the structures of warrior society—for example of Japanese landed estates with manors, and of Japanese income rights, granted to warrior families by the central government in exchange for military service, with fiefs—that often obscure the important differences between the two societies more than they illuminate their commonalities. This problem, too, is most critical in the Sengoku age, when massive daimyo armies must be explained, in the context of the feudal model, in terms of a more “impersonal and bureaucratic feudalism” than existed in Europe (J.R. Strayer, cited in Morillo 2003). “Bureaucratic feudalism” is a self-contradictory concept that dissolves on close inspection.

Application of the feudal model to Japan has also invited the equating of terms that occupy apparently analogous places in the model but that may not be so similar. The comparison of samurai to knights is the best example of this: the terms *knight* and *samurai* do not designate closely similar phenomena; the class connotations of the former make it closer to the *bushi* of pre-Tokugawa Japan. Equating samurai and knights also implies similarities between the fighting styles and techniques of the two kinds of warrior, when in fact their tactics differed significantly—especially, again, in the Sengoku age, with its samurai armies of disciplined massed infantry formations. The case of so-called feudalism in Japan thus serves as a caution against the hasty comparison of terms and models derived too narrowly from one culture.

A Term in Decline

In short, “feudalism” in world history is a historiographical phenomenon, not a historical one. “Feudal” and “feudalism” are terms that have failed to cohere into agreed-upon concepts. They purport to describe a type of society that is valid across cultures; but describing the fundamental elements of such a society entails imposing a Eurocentric privileging

of a European model that itself does not conform well to the most basic elements usual to a definition of the term. The alternative to clarity seems to be a broad definition of feudalism that fails to make useful conceptual distinctions among the societies to which the term is applied. As a result, it has become a term in decline.

Fire

Humans learned to control fire at least 400,000 years ago. Cooking over fire increased the variety of foods. Fire kept dangerous animals away from campgrounds and warmed living spaces so humans could leave tropical Africa and spread round the Earth; people burned dry vegetation as they migrated to improve hunting and thereby changed natural ecological balances. No single skill did so much to expand human power over nature.

The history of humankind is closely connected with the history of fire—so closely that the connection has become almost reciprocal. Of course, fire is much older than humankind; but ever since humans learned to exert some control over it, the frequency of fire and, even more, its manifold forms have increasingly been determined by human activities. Of all the fires burning on the planet Earth today, only a tiny portion have “natural” causes; in the great majority of cases the source of ignition has been human—intentionally or unintentionally.

These observations raise a whole range of intriguing problems concerning the history of the relationship between humankind and fire. How did this relationship begin? What were the conditions that made it possible? What were the feedback effects or functions that sustained it? How has the connection between humans and fire affected the course of history?

Our image of the first phases in the human domestication of fire was long dominated by mythology—as if the stories about Prometheus or other culture heroes who allegedly had stolen fire from the gods were the last word. Today we know better: with the aid of ecology and archaeology, of anthropology and

sociology, it is possible to reconstruct the general trajectory of the historical relationship between humans and fire.

Origins

Like all natural forces, fire has a history. Chemically, fire is a process of highly accelerated oxidation of matter (fuel) induced by heat (ignition). Three conditions are necessary for it to occur: oxygen, fuel, and heat. During the first eons in the history of the Earth, at least two of these—oxygen and fuel—were absent. Oxygen did not become available in the atmosphere until life emerged between three and four billion years ago. And it was less than half a billion years ago, during the Devonian geological age, when life assumed the form of plants, providing matter suitable for burning. From then on, most places on Earth with seasonally dry vegetation were regularly visited by fire, ignited on rare occasions by falling rocks, volcanic eruptions, or extraterrestrial impacts, but mostly by lightning.

Its domestication by humans opened an entirely new episode in the history of fire. Humans thoroughly altered the incidence and intensity of fires. They brought fire to regions of the planet where it seldom or never burned spontaneously, and they tried to banish it from places where without human interference it would have burned repeatedly. Thus, increasingly, “natural” fire receded and made way to “human,” or, more precisely, *anthropogenic* fire.

Wherever humans migrated, they took their fire along. The presence of humans-with-fire deeply altered the landscape, including flora and fauna. The

Eanger Irving Couse (1866–1936), *Indian by Firelight*. When handled carefully fire can protect against the cold and keep predatory animals at bay.

human impact is amply documented (though still controversial) for Australia—a continent that was colonized by humans rather late. Everywhere on the planet, areas such as rain forests, deserts, and the polar regions that were not receptive to fire proved to be hard to penetrate for humans too.

A Human Monopoly

Humans are the only species which has learned to manipulate fire. Control over fire has become a “species monopoly,” with an enormous impact on other species, both animals and plants, and on the civilizing process of humanity itself.

Evidence about the very first phase of the domestication of fire is insufficient and open to various interpretations. The most conservative estimates are from archaeologists who hold that the oldest undisputable evidence of human control of fire can be dated back at most 250,000 years. Other scholars, such as primatologist Richard Wrangham, argue that *Homo erectus* may already have been tending the remains of natural fires as long as 1.8 million years ago. According to the anthropologist Francis Burton, the turning point may be dated at even 5 to 6 million years.

While acknowledging these controversies over the actual chronology of the first domestication of fire,

we can still draw up some defensible propositions about its “phaseology”—the succession of phases. Three phases can be distinguished. During the first phase, there were no human (or hominid) groups possessing fire; there were only groups without fire. Then, there must have been a second phase, when there were both groups with fire and groups without fire. We do not yet know how long this phase lasted, but we do know that it was a transitional stage, leading up to the phase in which humankind has now been living for thousands of generations: the phase when there are no longer any groups without fire. For many thousands of generations, all human groups have been groups *with* fire.

The three phases are connected by two transitions. The first transition was marked by the initial domestication of fire by some human or hominid groups. Apparently they found it worthwhile not just to forage at the smoldering remains of a natural fire, but to see to it that the fire kept burning. They tended it, they protected it against rain, and they “fed” it with fuel. None of these activities were programmed in their genes; they had to be learned, and then transmitted, as traits of culture. But the *capacity* to learn all this had to be there, as a set of traits acquired in biological evolution. Those traits included physical features such as a bipedal gait, flexible hands, and a complex

A little fire is quickly trodden out; Which, being suffer'd, rivers cannot quench. • William Shakespeare, from *Henry IV*

brain, as well as concomitant mental and social features such as an ability to cooperate and to defer immediate gratification for the sake of consciously conceived goals.

Considering this combination of requisite traits we may find it almost self-evident that the control of fire became a monopoly, uniquely held by humans. The full significance of the monopoly can only be appreciated, however, if we regard it also in connection with the second transition, in which the monopoly became universally human. Whereas earlier hominid, and possibly human, groups had been able to survive without fire for many thousands of generations, a time came when apparently that was no longer possible.

If this sketch of phases and transitions is realistic (and it is hard to imagine why it should not be), it leaves us with an unavoidable conclusion: human societies with fire were in the long run more “fit to survive” than societies without fire. If we then ask why all societies without fire eventually disappeared, there seems to be only one plausible answer: because they had to coexist with societies *with* fire—and in the long run that proved impossible.

Implied in this line of reasoning is the idea that a change in some human groups led to changes in other human groups. If Group A had fire, and the neighboring Group B did not, Group B had a problem. It could either try to minimize contact with Group A, or do as Group A had done and adopt a fire regime—which should not pose insurmountable difficulties as long as the potential to learn from the other group was sufficient.

In terms of its formation and spread, the fire regime may be regarded as a paradigm for other regimes developed at later stages in human history—a paradigm in more than one sense. First of all, the regime by which humans learned to extend their care of and control over fire could subsequently serve as a model for taking care of and controlling other nonhuman natural resources such as plants and animals. Secondly, we may regard the domestication of fire as a model case in a “heuristic” or methodological sense, since it shows us some basic principles which are at work in social evolution and human history.

Hearths and Torches

The establishment of the species monopoly of control over fire amounted to a big step in the differentiation of behavior and power between humans and related animals, ranging from other primates to wolves or mammoths. As a new item in the behavioral repertory, tending fire tilted the interspecies balance of power greatly toward human dominance. The original breakthrough may have been precarious and fraught with risks; but it had far-reaching consequences—which were, of course, unforeseeable at the time. The history of the domestication of fire clearly illustrates the intertwining of intentional actions and unintended effects.

Fire became the focus of human group life in the form of the hearth. Here fire was tended and thus kept regularly available so that group members no longer had to go searching for it. Around the hearth they could create small enclaves in the wilderness where the nights were less cold and dark and which offered some protection against predators. On the fire itself they could cook their food—again a form of behavior which, like the domestication of fire upon which it is based, is both uniquely and universally human. Through the destructive force of fire, substances that otherwise would be too tough to eat, or even poisonous, could be made edible and palatable—a good example of “production through destruction” (or, to use the economist Joseph Schumpeter’s term, “creative destruction”).

A second way in which fire was used from early on was by lighting the end of a stick in the hearth and turning it into a torch. Torches could be applied to burn down dry vegetation, thus clearing land and making it safer and more hospitable for human habitation. Many prairies and similar secondary grasslands in various parts of the world were created by such burning practices. On a smaller scale, but no less effectively, humans could apply their torches to scare away big predators. Caves long inhabited by bears or hyenas were taken over by humans armed with fire.

This map shows the comparative areas of three major urban fires in U.S. history. Wherever buildings were constructed from wood, fire was a constant hazard and often spread quickly from building to building.

Fire and Socioecological Transformations

If fire was the first great socioecological transformation in human history, it was a precondition for two more that followed: agrarianization and industrialization. Both were far more momentous in scope, but neither would have been possible without fire.

The rise of agriculture and animal husbandry, or “agrarianization,” in many respects resembled the domestication of fire. Humans added new sources of energy to their own as they had done before by taming fire, this time by incorporating specific plants and animals into their societies. Certain wild plants were

cultivated, certain wild animals were tamed, and all these species were made part of the human domain, the anthroposphere.

In most parts of the world, the conversion of savannahs and forests into fields and meadows was accomplished by means of fire. Flames and smoke marked the frontiers of agrarianization—as they still do today in Amazonia and elsewhere. Often agriculture remained closely associated with burning, as in the widespread practice of swidden farming, or shifting cultivation, in which tracts of land would be periodically burned and cultivated and left fallow again for a number of years, in a cyclical sequence.

Many agrarian societies passed through a phase of shifting cultivation, but then adopted more intensive techniques of working the land with higher average yields. As these societies gave rise to villages and towns, new uses of fire and new attitudes toward fire developed. During the long first phase of human fire use, the main concern always had been to keep the communal fire burning. In the agrarian towns, however, fire was no longer scarce. Its uses became increasingly more varied. Specialized pyrotechnic crafts emerged, such as blacksmithing and pottery. Public concern now turned mainly to keeping the many fires within their containers. Fire was regarded with greater anxiety, for with the proliferation of fires the risks of conflagrations increased, and with the accumulation of property, people had more to lose. Not surprisingly, blazes figure prominently in the local histories of towns and villages.

Of course, the eventual cause of destruction always lay in the very nature of the combustion process. But with the progressive domestication of fire, this natural force manifested itself more and more through manmade fires. With all the lamps and furnaces burning in a city, one moment of carelessness might spark a conflagration. People had to rely on other people’s caution. Arson ranked second only to murder as a capital crime deserving the severest punishment. Among the worst fears of both farmers and city dwellers was to become

the victims of organized murder and arson known as war.

In the cities of medieval Europe it was mandatory to “cover” all fires before nightfall: an institution known as *couvre feu*, or curfew. The directive to cover fire almost symbolizes a general tendency in urban environments toward reducing the omnipresence of fire, and certainly toward making it less conspicuous. That tendency was interrupted for a while, however, by the onset of industrialization.

The Industrial Age

A highly significant, but rarely noticed, aspect of the original domestication of fire was the invention of fuel—the discovery that dead wood, seemingly worthless material lying around to rot, could be most valuable if it was used for burning. No other animal ever made this discovery. Nor did any other animal ever learn the great potential of fossil fuels.

During the ten thousands years of agrarianization, wood remained by far the most important fuel. This was to change dramatically in the course of the two hundred and fifty years of industrialization, starting in the early eighteenth century, when ways were discovered of exploiting other sources of fuel as well: coal, oil, gas.

Industrialization began, like agrarianization, with great displays of fire. Its frontiers were marked by the fire and smoke of steam engines driven by burning coal. Humankind was entering, to use the image of Rolf-Peter Sieferle, a newly discovered “subterranean forest,” containing the fossil remains of hundreds of millions of years of organic growth, stocked in the mantle of the Earth as unburned fuel.

Industrialization was the third great ecological transformation brought about by humans. It involved, once again, the tapping of newly exploited natural resources—first coal, later also oil and natural gas—and incorporating these into human society, as had been done before with fire and with certain selected plants and animals.

Just like the transition to agriculture, when forests were burned down to create fields and meadows, the

rise of modern industry was heralded by a huge and conspicuous use of fire. The familiar pictures of the early industrial landscape in Lancashire readily evoke the manifest ubiquity of fire, with smoke rising from the factory stacks at day, and a red glow illuminating the sky at night.

As industrialization advanced, fire continued to be important in practically every variety of industrial production; but its presence has become less prominent. The vital combustion processes tend to be hidden away, in the furnaces of power stations or under the hoods of motorcars. Partly as a result of this general tendency, cities in the advanced industrial world today are far better protected against the risks of fire than were preindustrial cities. The incidence of conflagrations in peacetime is much smaller now than it used to be until a few centuries ago. In times of war, however, the twentieth century has seen urban blazes of unprecedented size and intensity.

Current Developments

Ancient Greek cosmologists used to distinguish four elements out of which the world was composed: earth, water, air, and fire. While earth, water, and air are indispensable for all land animals, only humans have also come to rely upon fire. Furthermore, all known human groups have done so. The use of fire is not just an exclusively human attribute; it continues to be universally human as well.

In retrospect, we can detect a clear sequence in the history of humans and fire. First, there were no groups with fire. Then there were some with fire, but still none with fields cultivated for agriculture and animal husbandry. Then, there were some with fire and fields, but none with factories for large-scale industrial production. Today, all human groups take part in a socioecological regime extending over the entire planet, involving fire, fields, and factories.

For thousands of generations, the control of fire has deeply affected the human condition. It has made human groups, on the one hand, more productive and

robust, but at the same time also more destructive and more vulnerable. Seen in this light, the control over fire appears to be a double-edged sword, eliciting the same ambivalence that is typical of the present human self-image in general.

Nowadays fire is continuously present in all human societies. It is used in many different forms, some mainly ceremonial and highly visible, most others primarily technical and largely hidden from public view and consciousness. The moment we consider the part played by combustion processes in transport and production, it becomes clear how thoroughly our lives are enmeshed in structures which are kept going by fire and fuel. We live in highly fuel-intensive economies, and most fires burning today are generated by those economies. Fire has become overwhelmingly anthropogenic, or manmade. Where there is smoke, there is fire; where there is fire, there are people.

We may safely assume that every single step in the long-term process of increasing use of, and control over, fire has been the result of planned human action—of the deliberate and consciously steered efforts of individuals who knew what they were doing. It is more difficult to imagine that the increases in dependency were also deliberately planned. And it is extremely unlikely that our early ancestors in the foraging era ever drew up a comprehensive plan covering hundreds of millennia and leading all the way to our present plethora of gas furnaces and internal combustion engines; the very idea is absurd. Clearly the succession and interaction of short-term planned activities has produced long-term processes that were neither planned nor foreseen. Here is one more way in which the

control over fire can be seen as paradigmatic. It shows something of the stuff of which human history is made.

Food

Food is the collective noun we use to describe the vast range of animal and vegetable products that we human beings consume for nutrition and survival. At its most basic biological level, food is the fuel that is required by the body for biological functioning, and it is extracted from other organic matter in the form of energy. In order to live, we must eat food. Food also has a fundamental role in the formation of culture.

The act of exchanging food connects human beings with other species, with other human beings across diverse geographical regions, and with a notion of a divine being. Food is an integral part of world history on biological, social, and cultural levels because it is fundamental to networks of ecological and human exchange

Food connects humans with the plant and animal kingdoms within a complex web of interconnections, commonly called an “ecosystem,” thus bringing human existence into close symbiosis with the natural environment through processes of adaptation. Rock paintings in Europe, Africa, and Asia from more than twelve thousand years ago depict the collection of honey, one of humankind’s most ancient and durable foods, and represent the symbiotic relationship between flowers, bees, and human beings. From the Cheyenne people of the U.S. western plains to the Jews, from the Greeks to the Amazonians, honey has also been an enduring motif in the creation myths and legends of world cultures.

The act of exchanging food is central to social organization, to cultural identity and to religious practice. The great Hindu epic, the *Bhagavad Gita*, states that all beings come into existence from food. The ancient

Greeks worshipped Demeter (goddess of agriculture), and the Romans paid homage to their agricultural god Ceres (from whom we get the word *cereal*) in order to secure good harvests of wheat and barley. For the Aztecs, Chicomecoatl was the provider of maize from the heavens. The cultural importance of bread in both Christian and Jewish religious ceremonies is a further example of the cultural significance of food, and the Arabic term *halal* (sanctioned by Islamic law) and the Yiddish term *kosher* (sanctioned by Jewish law) remind us that rules of preparation and social interaction are guided by the sacred place of food in the human imagination. Moreover, the prohibition or reverence of certain foodstuffs in world religions (the taboo on eating beef for Hindus and the taboo on pork in Islam and Judaism, for example) speak of the symbolic role of “purity” and “pollution” in maintaining social rules of group inclusion and exclusion. In Hinduism, caste rules are maintained through complex and intricate food regulations designed to maintain social order.

Food Surplus and Emergence of Agrarian Civilizations

Archaeological evidence suggests that the earliest hominids (erect bipedal primate mammals comprising recent humans and extinct ancestral and related forms) in east Africa, *Australiopithecus afarensis*, probably ate roots, leaves, berries, and fruit as well as fish and insects that were caught by hand but that they did not consciously manipulate the natural environment. But not until the evolution of the direct ancestors of modern humans (*Homo erectus*) do we see changes in the varieties of food gathered and the

Open-air markets in Italy, famous for abundant and colorful displays, invite comparison shopping.

manner in which food procurement formed the basic structure of societal organization. In particular, in the hunter-gatherer groups of 100,000 years ago we see a way of life that was socially organized around the search for nutrition. Anthropologists have used their studies of hunter-gatherer groups such as the !Kung San of the Kalahari Desert in Africa, the Hadza of Tanzania, and Australian aboriginal peoples to provide a window into the world of preagricultural human communities. Sometimes called “foragers,” these groups had a mobile way of life with few possessions, moving from food source to food source and eating a wide variety of nutritious vegetables, seeds, berries, and nuts as well as hunting the occasional animal or catching fish. Food was shared equally throughout the social group. Depending on the availability of food in a given area, subsistence changed, and the group moved to exploit new areas for nutritional purposes. In terms of labor and energy usage,

hunter-gatherer groups have a relatively large amount of time to rest, sleep, and spend with each other in comparison with agricultural communities. For more than 90 percent of human history, the principal mode of food procurement was foraging.

The phenomenon of domesticating plants and animals with the intention of preserving food supply and the result of producing a surplus to hoard or exchange marks a fundamental shift in human history known commonly as “agriculture.” In simplest terms agriculture is the shift from food collection to food production involving what the historian David Christian calls “a shift from extensive to intensive technologies” (Christian 2004, 207). Due to the change in energy usage, the expenditure of labor power, and the fact that communities now tended to stay in permanent settlements, these practices gave rise to the emergence of the first agrarian civilizations. From the third to the middle of the first millennium BCE, these

civilizations were found only in Afro-Eurasia, first clustered around the fertile banks of the Tigris and Euphrates rivers in southern Mesopotamia and the Nile River in Egypt but later emerging in the Indus River valley of Asia and northern China. The cultivation of cereal crops and the subsequent domestication of animals in separate regions gave rise to a surplus of food that was used for hording, internal exchange, or external trade.

Food and Trading Networks

Foodstuffs were an important part of the trading networks of agrarian civilizations. Although staples such as wheat and millet in western Asia and rice in India and China always dominated internal trade, highly prized exotic and luxury food items were integral commodities of exchange along the ancient trade routes that linked civilizations. More than two thousand years ago Indian spices and coconuts were traded with the Romans in ancient Egypt via the seafaring route. During the time of trade along the Silk Roads from the Roman Empire to Han dynasty (206 BCE–220 CE) China, for example, foods such as anise seeds, dried dates, apricots, cherries, and pomegranates were exchanged. By far the most lucrative and profitable trade was in spices from the Malabar Coast of India, which was monopolized by Arab and Indian traders for centuries, pouring great wealth into the Indian Ocean area. Europeans in particular sought black pepper. In the heyday of the overland spice trade, the European demand for pepper meant that it was worth more in weight than gold, bringing social prestige to traders and bestowing wealth and opulence to cities such as Venice, which prospered during the Middle Ages to become a leading center of culture and commerce. The monopoly of the trade, however, and increasing demand for broader consumption pushed the quest to find an alternative route to the Islamic-Eurasian spice networks through European sea exploration. As an exchange good from ancient times to the fifteenth century CE, pepper typifies the manner in which specialized foodstuffs became commodities of high value in emerging commercial

networks, creating great profits for middle traders in particular. The trade in pepper ushered in the era of exploration as Europeans sought direct access to the market for lucrative spices.

The Columbian Exchange

The exploration of Christopher Columbus in 1492 did not find Indian spices but instead forged a new system of ecological exchange by which the trade in new foodstuffs would radically change global nutritional flows for the rest of human history. The opening of the sea route between Afro-Eurasia and the Americas brought together three world systems for the first time, and the European encounter with indigenous civilizations in the Americas would at once have a devastating effect on those civilizations as it also benefited the European quest for new lands, new markets, and new sources for better nutrition. The European encounter with the Americas was also a confrontation with species of plants and animals that were unknown in Europe and that had evolved in isolation due to unique patterns of evolutionary development. The subsequent transatlantic swapping of peoples, plants, animals, and diseases that culturally transformed both sides of the Atlantic is commonly known as the “Columbian Exchange.”

The discovery of new indigenous food sources in the Americas brought the emergence of new webs of commercial exchange that profoundly affected the European diet. New plant varieties, integral to the diets of indigenous Americans, Aztecs, and Mayans—such as kidney beans, peanuts, squash, peppers, pumpkins, pineapples, and avocados—were introduced to the European diet, whereas rice, wheat, barley, oats, coffee, sugarcane, bananas, melons, and olives came to the Americas from Afro-Eurasia. Of particular significance for the increase in trade to Europe was the introduction of the potato, which radically changed net yields of crops per acre, was higher in calories than any European grain, and provided a new source of carbohydrates that was to eventually become a staple food for the northern and western European working class during the Industrial Revolution. Indigenous

These drawings illustrate the variety of cooking utensils used over time and across cultures: (1) broiling sticks (Japan) and broiling fork (Sioux, North America); (2) gridiron (colonial United States); (3) stone frying pan (Korea) and frying pan on earthenware stove (Portugal); (4) soapstone baking dishes (Hupa, California); (5) pit oven (Samoa); (6) iron pan (United States); (7) boiling basket (Native American, northwest U.S. coast); (8) coiled boiling pot (Hopi, Arizona); (9) earthenware tripod boiling pot (Zuni, New Mexico); (10) shoe-shaped pot (Hopi, Arizona); (11) chafing dish; (12) rice boiler; (13) steamer.

peoples in the Andes of Bolivia were cultivating potatoes and other tubers ten thousand years ago. Maize was domesticated seven thousand years ago in the Tehuacán Valley in Mexico and produces almost double the yield of wheat. Maize was introduced to Afro-Eurasia for both human food and livestock feed, providing a new source of protein.

Sugar also was a lucrative food commodity whose production and trade were intimately entwined with the slave trade as a result of this new network of exchange among Europe, the Americas, and Africa. An expensive and highly prized commodity, sugar had reached both the ancient and medieval European worlds via Arab traders, but its production shifted to the Mediterranean by the fourteenth century. By the fifteenth century sugar production flourished in the Portuguese plantations in Algarve and Madeira due largely to the free labor of slaves who were transported from the west coast of Africa.

The opening up of the New World provided traders with an opportunity to satisfy the increasing demand for sugar as production moved to the Caribbean, where it began to thrive during the early sixteenth century. The expansion of the plantation system was

a direct result of the increasing demand for sugar in Europe. The demand increased as beverages such as coffee and tea became lower in price, lost their luxury status, and became popular with the masses. Cargo ships left Europe loaded with manufactured goods such as textiles, glass, tobacco, and gunpowder and headed for the West African coast, where these goods were bartered for slaves who were taken to the Caribbean and then to America to work on the sugar plantations. Sugar was the first major “cash” or export crop cultivated in the Americas to satisfy market demand in Europe, and its production using slave labor exemplified the exploitive nature of new global networks of food exchange that operated not to provide nutrition but rather to serve the interests of European capital and demand in a new global market.

Industrialization and Imperialism

Hence, Europeans colonized foreign lands and used slave labor to increase their supplies of food. Yet this was not a new political phenomenon. In ancient world societies with rising population growth, such

Economic reforms opened China to the world in the late 1970s. This menu at an Italian restaurant in Beijing in 2004 shows how global cuisine has permeated Chinese culture.

as Greece and Rome, an adequate domestic surplus was not sufficient to feed their own people. Through political conquest and military invasion, such empires secured plentiful food supplies from external sources. Hence, Greeks and Romans secured their wheat from Egypt and exotic fruits, such as cherries and peaches, and spices from the Mediterranean and Persia. During the modern era, however, as the population of Europe rose substantially during the nineteenth century, demand was even greater for an external food supply. That demand was created by quite different circumstances. The twin processes of overpopulation and industrialization caused mass emigrations from Europe across the Atlantic and to Australasia and a corresponding need to import large quantities of food from the rest of the world. This need created a global trade in foodstuffs on a scale never seen before in world history. In 1850 world exports of food were less than 3.6 million metric tons but by the 1880s had increased to 16 million metric tons and to 36 million metric tons by 1914.

The conversion of new lands for cultivation in places such as Argentina, Australia, and New Zealand during the nineteenth century and the appropriation of colonial food sources from Asia enabled people to import food items to Europe from overseas markets and to move bulk food items over long

distances in parallel with advances in shipping technology. Countries such as Britain shifted the focus of their food imports from exotic or luxury food items to the bulk staples that formed the basis of their diet, such as cereals, dairy products, and meat. By the early 1880s the use of refrigerated cargo ships enabled frozen animal carcasses to be exported from Australasia to Europe, allowing the export of bulk meat products. In sum this export was a movement of mass foodstuffs to feed millions of people. Moreover, the shrinking of the domestic agricultural sector in Britain in particular occurred in tandem with the consolidation of an overseas empire, creating a market for the export of manufactured goods to be traded for primary produce.

Entitlement and Deprivation

While food is an integral part of world history on biological, social, and cultural levels, it is also integral to the development of political movements, actions, and sensibilities. While the lack of basic foodstuffs due to poor harvests can lead to starvation, a natural shortage of food is not always the cause of a breakdown in food distribution mechanisms. On the contrary, food riots in world history have occurred when a breakdown in the entitlement to basic foodstuffs such as bread affected subsistence levels as a result of rising

Tell me what you eat, and I will tell you what you are. • Anthelme Brillat-Savarin (1755–1826)

prices. What the sociologist E. P. Thompson calls a “moral economy” amongst the poor develops to galvanize resistance to this deprivation, leading to a demand that prices be lowered so that subsistence levels are maintained. Protests about bread prices provided the political impetus for the events leading to the French Revolution of 1789 but they have also been a standard feature of revolutionary activity worldwide. The emphasis on the mechanisms of food distribution and exchange has also changed our understanding of famines. A widespread shortage of food leading to mass starvation has been a persistent phenomenon in world history. Famines occurred throughout Europe during the Middle Ages and the early modern period, especially in England and France, causing significant population decreases. Crop failures also caused widespread famine in China, India and parts of Africa. Nineteenth and twentieth century famines were characterized by their scale, devastating effect and the implications of political neglect. The Great Irish Famine of 1845–1849 emphasized the extent of that country’s dependence on the potato, a Peruvian tuber, but also on the pressing need for government assistance and support. The famines of the modern era have been located mainly in Africa and Asia where unequal distribution of resources and the impact of colonial rule have underscored nutritional vulnerabilities. While harvest failures and inclement weather conditions provide the precipitating conditions for mass starvation, it is often breakdowns in the distribution of available food that often leads to the inability of the poor to afford basic foodstuffs. Causes of starvation are often inflated prices for the available food and not a decrease in the overall food supply that underscores the politics of famine. The economist Amartya Sen’s famous analysis (1983) of the Bengal famine of 1943 provided an explanation of how the rural poor were deprived of the entitlement to food in a manner that the urban middle-class were not. As food prices become intimately enmeshed in the vagaries of global capitalism, food becomes a commodity to be sold and bought in a market where human need has become less important than profit.

Globalization and Crisis

These changes in the manner in which food is distributed and exchanged on the world market have meant that the need to fulfill nutritional requirements has been replaced by the needs of global capital. Food has changed from being a source of nutrition exchanged for the purposes of survival to being a commodity traded for profit in a global system of trade, a phenomenon that has benefited the West. Processes of economic and cultural globalization leading to the rise of an affluent middle-class in parts of Asia, Africa, and Latin America has seen “fast food” culture transform urban eating habits across the world. The rise of the global “fast food” outlet has been perceived as a process of rampant Westernization where the erasure of cultural differences and the transformation of local eating habits have mirrored the homogenizing effects of global capital.

The difference between global “fast food” culture and the nutritional struggle of the world’s poor could not be starker. With food prices indexed to inflation and currency exchange rates, fluctuation in value often means that the poorest communities in developing countries cannot afford it. The division between “developed” and “developing” nations and the continued prevalence of famine in parts of Africa and Asia are the legacies of this unequal distribution by which networks of commercial food exchange have favored both the appetite and the economic growth of the West. The global financial crisis was in many respects precipitated by a world food price crisis bringing economic uncertainty and social unrest to many parts of the developing world. The price of basic staples has risen beyond the reach of the poor. The specter of the bread riot has re-emerged in recent years in places such as Egypt and Mexico as a timely reminder that access to basic nutrition is a social entitlement rather than an economic privilege.

Foraging Societies, Contemporary

Until about 10,000 years ago, humans of all cultures were foragers who gathered their food from the natural environment. Although purely foraging societies no longer exist, some peoples involved to varying degrees in economies and political systems still rely on foraging lifeways. The study of modern foragers can provide historians with knowledge, albeit limited, about the diversity of human experience.

Anthropologists call human groups who subsist by collecting foods from the natural environment *foragers*. Unlike food producers—groups who subsist by herding, gardening, or farming—foragers grow little or no food of their own. They hunt animals, fish, and gather plants, reptiles, insects, and other food-stuffs. Because their primary forms of food acquisition are hunting and gathering, they are also commonly referred to as hunter-gatherers or collectors.

For the 2–3 million years of human existence up to about ten thousand years ago, all humans were foragers, and therefore all cultures were foraging cultures. Foraging began to be replaced by herding and farming in western Asia about ten thousand years ago, and since then the percentage of humans who are foragers and cultures that are foraging cultures has steadily declined. In the modern era (since about 1750) foraging has been the primary subsistence strategy of only a very small percentage of people on Earth. As foraging peoples have come into contact with or under the rule of nation-states, many have disappeared, been absorbed into the dominant culture, or been reduced to a marginal existence on the fringes of society. Dominance by modern nation-states is now so complete that in 2010 there

are no purely foraging cultures, and there probably have not been any for several decades. Sensational claims in the media of the discovery of Stone Age peoples, such as the Tasaday of the Philippines in 1971, have proven on closer examination to be false or exaggerated. Those peoples that have continued to rely on foraging lifeways in recent times have rarely lived entirely independently and have been involved to varying degrees in local, regional, national, and global economies and political systems.

If modern foragers are so few in number and have minimal political and economic significance, why are they important in world history? They have drawn and continue to draw attention that far exceeds their numbers because they are viewed as surviving representatives of the foraging (Paleolithic) era, from whom it is often assumed that we can learn about the human past. Unfortunately, while the study of modern foragers can and does inform about the diversity of the human experience, much recent research suggests that there are narrow limits to what can be learned about our foraging ancestors from the ways of life of foragers in the present.

Distribution and Lifeways of Modern Foragers

In modern times foragers have lived on every continent except Europe, although their distribution has typically been limited to specific regions. In North America, modern-era foragers included the Inuit peoples of Alaska, Canada, and Greenland, the desert peoples of the American West; and the forest peoples of the northwest coast, the Great Basin, and the subarctic regions. In South America foragers were encountered

A Native American pictograph shows a buffalo hunt in progress.

in Amazonia, the Grand Chaco, and Tierra del Fuego. In Africa there were two major dispersals—in the tropical rainforests of central Africa and in the Kalahari Desert in the southwest. In Asia, foragers were found in the rain forests of the south and southeast (in India, Sri Lanka, Malaysia, Indonesia, and the Philippines) and in Arctic Siberia. Finally, in the Pacific, the aboriginal peoples of Australia were foragers. Among the foragers who have drawn considerable anthropological and popular attention are the Mbuti and Efe of central Africa, the San of Botswana, the Andaman Islanders in the Andaman Sea, the Copper Eskimos in Alaska, the Chukchi in Siberia, the Ache of Paraguay, the Yir Yoront and Tiwi in Australia, and the Semang and related groups in Malaysia.

Anthropologists now recognize that foraging societies are similar to one another in many ways, but they also differ in significant ways. The key difference is one of scale, with some groups being small and having a relatively simple social and political organization, while other groups are more complex, with larger populations and more specialized and differentiated social and political systems. To some extent, this variation is best viewed as a continuum, from simple to complex or, as it is sometimes labeled, from classic foragers to affluent foragers. Some of the

better-known foragers fall at the classic end of the continuum; these include the Mbuti, San, Inuit, and many Australian Aborigines. Among those at the affluent end of the continuum were the Ainu of Japan, the Tlingit and several other cultures of the Pacific Northwest, the Tiwi, and several native peoples of central and northern California.

Classic foragers lived traditionally in small, migratory bands of less than a hundred people. They moved about to seek the best living conditions and to acquire food. Movement was not random, but was based on experience and knowledge of nature. The basic social group was the nuclear family of a father, mother, and their children. Bands were formed by groups of related families and grew or shrank in size in accord with available natural resources such as water, game, and plant foods. Social relations were based on ties of kinship, friendship, and trading partnerships. Exchange was based on reciprocity, and in the absence of personal property, sharing was the rule. The division of labor was based on sex and age, with women usually doing all or most of the gathering of plants and other foodstuffs, water, and firewood and caring for the children. Men did the hunting, sometimes alone and sometimes in groups, and were usually responsible for dividing the products of the hunt and for trading with other groups. Food was consumed soon after it was obtained. Conflict was resolved through gossip, physical fights, public ridicule, and ostracism. Leadership was fluid, generally going to the person best at the task, although men with much kin support or with oratorical skills might occupy a position of informal leadership. In some cultures animism and shamanism were the religious systems, with the environment often seen as uncertain and even hostile. Religious ritual generally centered on influencing the supernatural world of spirits and other forces to look and act benevolently toward the human world.

The key difference between classic and affluent foragers was that the latter lived in richer environments and thus were able not only to collect but also to process and store food for future use. The Tlingit gathered salmon and other fish in large quantities from spawning streams, and Native American

groups in northern California gathered acorns and processed them into flour. Affluent foragers also developed more sophisticated technology to exploit the environment. The rich environment and steady supply of food led to other differences from classic foragers. Affluent foraging communities were larger and permanent or semipermanent. There was more personal property, and there was occupational specialization, with some people acting as leaders, some specializing in crafts, such as canoe making, and some acting as religious specialists. Social status based on wealth, personal abilities, and family status was the rule, and individual families were defined in terms of their place in larger lineages or clans. Leaders of these larger kin groups were usually men who were socially adept at managing kin relations and marrying off or marrying in women to create kin networks loyal to them. The economic system was based on trade, not only of goods but also of personal services. As with classic foragers, conflict was not unknown, and relations with neighboring groups were often hostile.

Impact of the Outside World

The impact of the outside world, and especially of Western colonists on modern-era foragers, has been shaped to a significant extent by several stereotypes of foragers. Perhaps the earliest stereotype, adhered to by many colonial officials, soldiers, and missionaries, was that foragers were primitive savages who were intellectually and morally inferior to the colonizers and who needed to be civilized and converted to Christianity. This view empowered colonial officials and their agents to take land and other resources, enslave foragers, relocate them, force them to convert to Christianity, remove their children for education in white-controlled schools, and enmesh them in a market economy. It also empowered scientists to study them as objects, to acquire, store, and exhibit forager material culture in museums, and in some cases to exhibit the foragers themselves or bones of their ancestors.

In many cases, what the colonists most wanted was the valuable natural resources found in the

A Tohono O'odham (Papago) woman in Arizona collects fruit from a giant cactus.

traditional territories of foragers. Those resources included sea mammals, fish, animal fur, minerals, trees, and the land itself for use in farming or ranching. Given their small numbers and lack of sophistication, foragers were rarely able to offer much resistance, and many individuals and groups disappeared either through extinction or assimilation. Perhaps the most notorious case was the purposeful hunting down and killing of the Tasmanians by agents of the British Empire, which left no pureblood Tasmanians on Earth by the twentieth century. As destructive as colonial actions were, the infectious diseases that colonialists brought with them were equally or more destructive. It is not hard to understand, therefore, why the foraging lifeway has disappeared as a distinct type of culture.

Purepecha Indians in central Mexico fish with traditional style, butterfly-shaped nets used for centuries by their ancestors.

A version of the noble savage stereotype, which developed in the 1960s, was the near opposite, with foragers idealized and romanticized as Earth's first environmentalists, living in harmony with nature. Because their numbers were small, it is true that by and large foragers have left a much smaller ecological footprint on the Earth than have food producers. But it is also true that affluent foragers often heavily exploited the environment and sometimes used wasteful techniques, such as driving animals over cliffs or netting enormous numbers of fish, to obtain what they wanted. In addition, since many modern-era foragers lived in economically marginal environments, they tended to view the environment as an uncertain and even hostile place.

Since the 1960s, as part of the broader indigenous rights movement, some foragers have used public opinion and the political and legal system to regain some rights, including political representation, control or ownership of some of their traditional territory and natural resources, and the return of their material culture and remains of their ancestors. Among the success stories are the growing indigenous rights movement in post-Soviet Union Siberia, protected areas set aside for groups in Brazil, legislation in the United States mandating the return of remains and material culture to Native Americans, the establishment of the Inuit homeland of Nunavut in northern Canada, and the legal recognition of land rights for Aboriginal peoples in Australia.

Learning from Modern Foragers

Anthropologists now generally agree that foragers in the modern era cannot be considered living guides to the lifeways of foragers of the past. This is the case for several reasons. First, no presently existing foraging society is a simple survival from the past. Rather, every society has its own history and has changed over time. Second, some contemporary foraging societies were not always foragers. For them foraging is a recent adaptation to the environment and represents a devolution from a former lifeway based on gardening or farming. Third, nearly all foragers of the modern era live in harsh environments—deserts, tropical forests, the Arctic north—while foragers in the past lived in a wider range of environments, some of which were less hostile to human existence.

Fourth, most foragers of the modern era did and do not live in isolation. Rather, they have had extensive and long-term exchange relations with other foragers and nonforagers. For example, many aboriginal groups in Australia were directly or indirectly involved in trade with the Chinese and Malay for hundreds of years. Some Bushmen groups in south-west Africa have lived a symbiotic existence for over a thousand years with neighboring Bantu-speaking farmers and herders. After Western contact, foragers in North America and Siberia were quickly drawn into the fur trade. And some anthropologists argue that tropical forest foragers such as the Mbuti in the Congo have always had trade relations with neighboring farmers.

Fifth, in the twentieth century all foragers that were not already so involved have come under the political control of nation-states and become part of local, regional, national, and global economic exchange networks. For example, forest products such as soap produced by foragers in Amazonia, bark art created by Australian aboriginals, and soapstone sculpture by Inuit peoples are all marketed internationally.

Despite these limiting factors, there is some recent research that suggests that we can learn something about the human past from modern foragers if we are

careful about what questions we ask and what information we use to answer those questions. For example, the lifeways and adaptations of modern foragers do tell us something about how humans adapt and have adapted to different and changing environments. Social relations among foragers tell us something about conflict and cooperation and the significance of kin relations in human evolution. Forager worldviews and religious beliefs tell us something about human cognitive processes. Finally, comparison of foragers with other primates can tell us something about the life course of prehistoric humans and the evolutionary processes that shaped the human journey. Research on these and other questions is in its early stages and may well produce noteworthy findings.

Freedom

The understanding of freedom as “an absence of restraint” took shape with the Protestant Reformation in the early sixteenth century: religious freedom represented a denial of church authority. This view is vastly different from that of most cultures in world history, including Europe until the Renaissance, where freedom was understood as the opportunity to fulfill human potential.

Defining the term *freedom* poses several challenges for world historians. (Freedom is usually regarded as synonymous with liberty, the term *freedom* being a descendant of the German language and *liberty* of the French. Some commentators use liberty to refer primarily to the political context of freedom.) In the modern West (itself a problematic term, here defined as Europe and its cultural descendants in places like North America), freedom has most typically been understood in a negative sense, as an absence of constraint. In most other cultures in the world, however, as well as in Europe itself until the Renaissance, freedom was—and is—more often understood in a positive sense as representing the opportunity to fulfill potential that is latent in the human personality. This essay will first consider the modern definition, then the global (and traditional Western), concluding with some reflections on the larger significance of freedom.

Modern Definition

The dominant modern Western understanding of freedom as an absence of constraint is a consequence of numerous developments beginning with the Protestant Reformation. The assertion by Martin Luther

at the beginning of the sixteenth century that the individual conscience is the ultimate arbiter of orthodox doctrine undermined the universal claims of the Christian church. Religious “freedom” thus came automatically to represent a denial of the authority of the church. At the same time, the philosophical school of natural law—by that time a synthesis of Stoicism, Aristotelian thought, and Christian theology—began to change its focus from an emphasis on duty to an emphasis on rights. The conviction grew that the individual was an autonomous (that is, a “law unto oneself”) moral and political entity over which the church, and then the state, had only limited authority. To assert a “right,” therefore, meant to throw off the chains, or constraints, of those in either ecclesiastical or political power—hence the emphasis on negative freedom as an absence of constraint.

In its modern political form, this worldview contributed to the doctrine of popular sovereignty and liberalism. In some cases, it also contributed eventually to the rise of democratic institutions in the modern West beginning in the United States and Great Britain. To be sure, democracy had existed elsewhere as well. It may well have characterized the participatory interactions of hunting-gathering societies before the advent of agriculture. Nevertheless, most historians believe that the roots of historical democracy lie in the West, where it flourished for a short time in classical Athens and republican Rome before disappearing for 1,500 years. After reappearing briefly in the city-states of Renaissance Italy, it then took on its modern form only after the rise of the nation-state in the seventeenth and eighteenth centuries, first in the United States and Great

Eugène Delacroix, *Liberty Leading the People* (28th July 1830). Oil on canvas. The painting commemorates the rebellion that brought Louis-Phillipe to the throne. Musée du Louvre, Paris.

Britain and then gradually spreading elsewhere in the last two centuries.

The economic expression of this modern understanding of freedom as an absence of constraint was best expressed by Adam Smith's theories of liberal capitalism, embodied in *The Wealth of Nations*, published in 1776. There he argued that the most efficient and productive economy is one in which individuals in the marketplace are allowed to make choices without interference by the government. Adam Smith's views were eagerly appropriated by the middle class in Britain, intent upon removing all obstacles to free trade (thereby increasing their profits). From that time on, the philosophical basis of liberal capitalism—expressed most notably in the twentieth century by Friedrich von Hayek—has been this definition of freedom.

The social counterpart of laissez-faire economic doctrine in the modern West was the social contract theory, which began with the work of thinkers like Thomas Hobbes in the seventeenth century. This theory holds that in a state of nature human beings are entirely solitary. At some point they realize that the benefits of living together outweigh the loss of some of their natural freedoms, which sociability requires them to surrender to society. Society, therefore, is

held to be an artificial construction of the individual human will, whose purpose is to serve the interests of the individual. The individual is primary; the society is secondary. The rights of the individual thus take precedence over duty to society, the purpose of the latter now being only to serve the former.

Global and Traditional Western Views

The modern Western understanding of freedom and rights is separated from that of the rest of the world, and from the traditional Western understanding, by a vast gulf. From the perspective of most cultures in world history, freedom was understood in its positive sense, as the opportunity to fulfill the human potential. In its political form, freedom was a condition that could not be separated from its complementary partner, namely, responsibility (or duty). Like two sides of a coin, each was understood to have meaning only in relation to the other. Politics, therefore, was inseparable from morality. The purpose of government was not to cater to individual wants, but to foster a society that fulfilled the noblest aspirations of the human personality. For the early Greeks, for example, that meant serving the community through perfecting

Mural with Martin Luther King Jr. and Winston Churchill, two of the most influential leaders of the twentieth century, in Battery Park, New York, August 2001.

the rational and moral faculties. In all cases, it was assumed that the purpose of life was not primarily to serve oneself but to serve others, and the proper exercise of freedom—or choice—was therefore to carry out one's responsibility to the common good. In this understanding, politics was also education, in the root sense of the term, to "lead out" (*e-ducere*) that which is latent in each individual. Education and politics and morality, then, were intimately linked with freedom.

In its social context, this traditional, and global, understanding of freedom worked itself out in much the same way. The relationship between the individual and society was not adversarial but complementary. Freedom was understood to be not a natural attribute of individual autonomy but a gift that can exist only within the larger context of social responsibility and moral authority, without which it degrades into license. The purpose of freedom, therefore, was to carry out the responsibilities that come with each role we are called to play in life. In India, for example, those responsibilities were expressed in following the dharma (law), appropriate to one's station in life.

In the economic realm of the premodern West, as well as most of the rest of the world, freedom and politics have been closely related. In the premodern context of world history, the role of government was not usually seen as inhibiting prosperity but facilitating it. The doctrine of mercantilism, against which Adam Smith wrote his masterpiece, embodied this understanding. The freedom of merchants to conduct their business depended on the peace and security (and high tariffs) provided by the state. Whether one speaks of the economic prosperity of the Mediterranean world under the Pax Romana or the countries served by the Silk Roads, the political responsibility of states to maintain law and order guaranteed the economic freedom of merchants to trade. Obviously, of course, when the state failed to carry out those responsibilities and became itself an instrument of oppression and exploitation, the economic freedoms of the people were compromised. When that happened, prosperity usually declined, and with it the eventual power of the state as well. To some degree this paradigm still holds true, as when critics of globalization argue that the real culprit is not the global

Whatever the man in authority said, it was not pleasant. Whatever the man in authority said, it was not right. • **Sumerian Proverb**

trade itself but the absence of a global structure of law capable of punishing those who abuse their power.

In its religious forms, the positive understanding of freedom contains a fascinating paradox in which the differences between it and the negative understandings of freedom tend to dissolve. From a negative perspective, freedom manifested itself as a liberation of the immaterial soul from the constraints of the material body [for Christians, it was salvation; for Hindus *swaraj* (self rule) and *moksha* (liberation), for Buddhists nirvana (extinguishing of self)]. From a positive perspective, however, this liberation could come only by surrendering oneself entirely to one's duty or to God's will. The only way to transcend constraint, in other words, was to accept constraint. The religious realm of human freedom also raises profound moral questions about the nature of good and evil. Put simply, the freedom to choose between good and evil, or right and wrong, implies that some will choose the former and others the latter. Evil, or suffering, in this view, is a necessary price of freedom. The most famous exposition of this problem is contained in Fyodor Dostoyevsky's (1821–1881) rightfully famous chapter from *The Brothers Karamazov* entitled "The Grand Inquisitor," in which Christ returns to Earth during the Spanish Inquisition only to be arrested by the Grand Inquisitor himself and interrogated in prison. In a long monologue, the Spanish priest accuses Christ of having made a tragic mistake by giving freedom to humankind. No sooner do people have the power to choose, he asserted, than they abuse it by making choices that cause needless suffering to themselves and others. Better to take away their freedom and force them to do what is right. Since the Grand Inquisitor's proposition leads to tyranny, of course, we reject it, but often without remembering that the possibility of freedom—which insures that some will choose badly—contains a tragic imperative that can be mitigated but never eliminated.

In its artistic incarnation, freedom takes the form of the creative power of the imagination to express the deepest yearnings of the human spirit. The creative impulse in the human personality has been

evident from the very earliest transition to modern *Homo sapiens* 100,000 years ago. Tools and ceramics were made to be not only practical but also beautiful. The astonishing diversity of cultural expression throughout the world, in every realm, whether music, dance, literature, painting, sculpture, ceramics, or a host of others, is wonderful testimony to the creative power of the human imagination. Those who worry that globalization will inevitably bring about an inevitable homogenization of culture can derive some comfort from knowing that this drive for freedom will resist that process. Cultural interaction, in the end, has been both a stimulus for artistic development, as well as, occasionally, an obstacle. The Silk Roads, for example, brought many influences from West to East, and vice versa, but in all cases the cultural life of the Eurasian continent was immeasurably enriched. Some of the most splendid examples of world architecture, such as the Taj Mahal, are witness to this remarkable capacity of humankind to absorb influences from without and then produce a synthesis that represents an entirely new level of achievement.

In science and technology the exercise of freedom in developing new tools has vastly increased the power of the human species to dominate both nature and other people. In terms of the interaction between people and the environment throughout world history, freedom has made it possible for humans to control the processes of nature far more than any other animal, but has also, especially when divorced from its complementary twin—responsibility—raised the specter of the potential extinction of the species. The tragic, as well as the beneficial, potential of human freedom is perhaps best illustrated by the progress made in the last 10,000 years in technology and science. The domestication of fire, for example, brought about a much greater array of human freedoms than ever before—humans conquered the night, overcame the seasons, and migrated to all regions of the world. But fire can destroy life as well as serve it. Just as a knife can kill game, it can also kill one's neighbor. Every advance in choice brought an equivalent burden of responsibility, right down to the detonation

of the first atomic device in 1945. It was, in fact, a failure of ideas and institutions to respond responsibly to this tragic potential of science and technology that led to the terribly destructive world wars of the twentieth century. Whether the human species, at the dawn of a new century and a new millennium, will be able to balance our new technological freedom with responsibility and thus avoid extinction is an open question.

In world histories written in the nineteenth-century West, freedom was the core organizing principle for a generation of historians who inherited the Enlightenment faith in progress and saw all history as the gradual growth of human freedom. The great German philosopher Georg Wilhelm Friedrich Hegel even went so far as to remark that all human history is an unfolding of the consciousness of freedom. In the twentieth century, however, historians shied away from freedom as an organizing principle. Perhaps freedom had been so intimately linked with the nineteenth-century faith in progress—blasted to bits by World War I and II—that it no longer seemed relevant. In any case, for those involved in political movements that sought deliverance from colonialism or other forms of oppression, freedom has remained a core value. From Mohandas Gandhi to Martin Luther King to Nelson Mandela and Desmond Tutu, the human quest for freedom was far more than an intellectual exercise. Their example, and that of all those alive today who continue to struggle and suffer in the name of freedom and human rights, remind us that the highest expression of freedom is to serve the noblest values of the human spirit.

Implications

Freedom, in its negative sense of an absence of constraint, has been identified in this essay as the underlying ideology of liberal capitalism and (in the nineteenth century) of human progress. This optimistic view of capitalism, it should be said, was challenged by socialists who held that free-market competition had produced an unacceptable level of

inequality and exploitation. The ensuing conflict between those champions of capitalism on the right who defined justice in terms of freedom and those advocates of socialism on the left who defined justice in terms of equality has lasted to the present and shows no signs of disappearing. The former praise globalization; the latter attack it. Both assume that freedom and equality are incompatible, and that an increase in one can come only with a decrease in the other. The two sides might find more common ground for agreement if they were to take an intellectual bath and then change into a new suit of definitions. By defining freedom in its positive sense as human fulfillment, and defining equality in terms of opportunity rather than condition, the proponents of “capitalist” and “socialist” views of the world might discover many of their differences melting away. In addition, they would be much more likely to cooperate effectively to reduce what both find most harmful to human progress, namely global poverty. If it is true, as the nineteenth-century writer Samuel Taylor Coleridge is once supposed to have remarked, that people are usually right in what they affirm and wrong in what they deny, then one could argue that each party in this dispute is right in affirming its own definition of justice and wrong in denying the other’s. In the end, the richest fruits of freedom are to be found through a positive understanding of its deepest meaning.

French Empire

The French Empire, which began in the early 1600s, developed sporadically and in successive stages of gain and loss, establishing colonies in North America and the Caribbean, and in West Africa and Indochina, until it reached its heyday in the 1930s. By 1960, having lost its African colonies and Vietnam to independence, the French Empire ceased to exist.

The first French Empire was founded in the seventeenth century. Around 1600 the French had begun to travel to Asia, and in 1604 the French East India Company received a royal charter. This enterprise was not a success, however, and its activities were discontinued in 1609. In 1642 the Company of the East was founded, which never really got off the ground either. In the same period French colonization in North America (Canada, Louisiana) and in the Caribbean (Martinique, Guadeloupe, Saint Domingue) had also begun.

Under the monarchy, France built up a colonial empire of consequence, but by the end of the Seven Years' War (1756–1763) most of it had been lost. Under the terms of the Treaty of Paris (1763), France's Louis XV (1710–1774; reigned 1715–1774) relinquished to England all of France's possessions in North America to the east of the Mississippi and ceded to Spain all French possessions to the west of the Mississippi (in 1803 Napoleon would recover the latter possessions from Spain and subsequently sell them to the United States, the so-called "Louisiana purchase"). France also gave up all political claims to India. This largely put an end to the first French colonial empire. What remained, however, was the French West Indies (French Antilles), which became very

important in the eighteenth century. The pearl of the French West Indies was Saint Domingue—the French, western part of the island of Hispaniola (present-day Haiti and the Dominican Republic). The basis of the French West Indies' prosperity was sugar and coffee, grown on the islands, which only French companies were allowed to trade. The French West Indies, which produced half the world's sugar and coffee, were the richest colonies in the world. In the second half of the eighteenth century Saint Domingue became the largest producer of sugar in the Caribbean. In the 1780s it also produced half the world's coffee.

The French Revolution put an end to the economic foundation of the French colonial economy, namely, slavery. After the revolt in 1791 led by Toussaint Louverture (1743?–1803), Saint Domingue was lost to France. Napoleon reintroduced slavery, however, and tried to regain control of the island. This resulted in a war, which lasted until 1804, when Saint Domingue gained its independence and changed its name to Haiti. During the days of Napoleon (1769–1821; reigned as emperor 1804–1814, 1815), France itself became an important producer of beet sugar, and therefore the interests of the sugarcane planters overseas had to be weighed against those of the sugar beet farmers at home. During the same period, the English took possession of the remaining French colonies one by one, and only a few of them were eventually restored to France. By 1815, therefore, France had very few colonies. The only French possessions in the Indian Ocean were the island of Bourbon (called Réunion after the French Revolution) and a few trading posts on the coast of India, such as Pondicherry. On the western coast of Africa, the French held sway in a few cities in Senegal, such as Dakar, Saint-Louis, and Gorée. France's most

important colonies were still those in the West Indies: Martinique, Guadeloupe, and several smaller islands and, on the mainland, French Guyana. But they were no longer as important as they had been.

A Colonial Interlude, 1815–1881

The Bourbon monarchs, who were restored to power after the defeat of Napoleon, were not very interested in colonial expansion or in military adventures. All the same, the final act of the last Bourbon king, Charles X (1757–1836; reigned 1824–1830), was to launch an expedition to Algiers. The reasons for this are to be found in French domestic politics. The

regime was very unpopular and the only means of restoring its prestige—or so it was thought—was to launch a successful military expedition. Therefore on 31 January 1830 the decision was taken to send an expeditionary force to Algiers to punish its ruler (the dey) for an insult inflicted on the French consul.

On 14 June 1830 the French troops landed, and on 5 July the dey surrendered. It was too late, however, to save the Bourbons: Charles X fled the country after the July revolution, which brought a new king, Louis-Philippe of Orléans (1773–1850; reigned 1830–1848), to the throne. The new king did not know what to do with Algeria. The aim of the expedition had been to punish the dey, not to turn Algeria into a

French colony, although that happened all the same. The French decided to stay, and eventually Algeria became France's most important overseas possession and its one and only colony of settlement. The surrender of the dey had been quick, but it was a long time before the country was under French control. Abdelkader (1808–1883) was the very capable leader of Algerian resistance, and he defeated the French on several occasions. The French marshal Thomas Robert Bugeaud (1784–1849), who knew about guerrilla warfare from his years in Spain during the Napoleonic era, finally prevailed, eliciting Abdelkader's surrender in 1847.

A colonial administration was set up. Algeria was considered a part of France and administratively followed the French model. There were three *départements* (provinces) each with a prefect at its head, who was directly responsible to the minister of the interior in Paris. This so-called assimilation policy would later become the model for French colonial administration in general.

During the reign (1852–1870) of the emperor Napoleon III (1808–1873), France saw some colonial revival. An active policy was followed in West Africa whereby the old French possessions in Senegal formed the base for further colonial expansion. Under Napoleon III, France also became active in Indochina (present-day Vietnam, Laos, and

Cambodia). The reasons for this were partly economic (colonial expansion was increasingly seen as a means of promoting economic growth, particularly in port cities and industrial cities such as Lyons, Bordeaux, and Marseilles) and partly political: the British and Americans had become active in East Asia, and if France was also to continue to play a role there, the feeling was that it had better hurry up.

In 1859 the French took Saigon, and in 1862 the Treaty of Hue, signed by the emperor of Annam (a kingdom in the eastern portion of present-day Vietnam) granted France sovereignty over Saigon and the neighboring area. In 1863 the King of Cambodia placed himself under French protection. But, like in Africa, true French expansion in Indochina did not gain momentum until the Third Republic.

The New French Empire, 1881–1962

After France's defeat in the Franco-Prussian War of 1870–1871, there was only one urgent call: *revanche!* (revenge). Therefore in the beginning colonial expansion was out of the question. But by the 1880s, as revenge turned out to be an illusion, new ideas about French foreign policy developed. Propagandists of colonial expansion argued that it was possible to restore French grandeur by expansion overseas. The main advocate of this policy

was Jules Ferry (1832–1893) who served as prime minister from 1880 to 1881 and again from 1883 to 1885. Ferry was not only the man behind two major interventions (in Tunisia in North Africa and in Annam and Tonkin in Indochina), he was also a colonial theorist. His motives were partly economic (he advocated the export of capital and goods, not of people), partly humanitarian (the higher races, he reasoned, had a duty to civilize the lower ones), but primarily political: he wanted France to recover her former glory and to take up her place in the sun.

North Africa

The first French expedition was to Tunisia. An incident on the Algerian-Tunisian border provided the pretext. A French expeditionary force crossed the border and marched for Tunis. On 12 May 1881 the bey (head of state) of Tunisia signed the Treaty of the Bardo, which placed Tunisia under French protection. The protectorate was a new concept, and implied that the bey would remain sovereign in name. In fact, however, the French representative (with the title of resident-general) was all-powerful. The protectorate formula was later also used in Indochina and Morocco. It was a break with the French tradition of assimilation and direct rule, though in actual practice the protectorates were almost as strictly controlled by the French as the colonies proper.

With the acquisition of Tunisia the eastern border of Algeria had been secured, but not the western border, with Morocco, and thus that country now became of compelling interest to France. The Sherefian Empire, as Morocco was known at the time, was in decline in the nineteenth century. European penetration took place in an informal way, by economic influence and special privileges for Europeans. Spain, Italy, Britain, and Germany were France's competitors for influence in Morocco. France compensated Britain for giving up its claims in Morocco by permitting Britain a so-called free hand in Egypt; Italy was compensated in the same way with Libya. Spain was promised a part of Morocco, and after two major diplomatic crises, Germany was compensated elsewhere (in western

Jacques Cartier claiming Canada for the King of France in 1534. The French Empire expanded sporadically; by the seventeenth century it also included Louisiana.

Africa). After that it was possible for France to install its protectorate in Morocco in 1912. However, it took a long time before the whole of Morocco was effectively brought under French control. The name of Louis-Herbert-Gonzalve Lyautey (1854–1934), the first resident-general of Morocco, is inseparably connected with the subjugation of Morocco.

In 1911 Algeria's population was 5 million, 715,000 of them Europeans, of whom 500,000 were French. The European population was concentrated mainly in the cities, the most important of which were the capitals of the three *départements*: Algiers, Oran, and Constantine. There were also colonists elsewhere who engaged in farming and winegrowing; the state put free land at their disposal. After the Franco-Prussian War of 1870–1871, most of those who took advantage of this opportunity were Frenchmen emigrating from the regions of Alsace and Lorraine that had been transferred to Germany. Tunisia's population was much smaller. In 1911, of a total population of just over a million, there were 148,000 Europeans (the great majority of them Italians, not Frenchmen). In Morocco, European immigration had

also been concentrated in the port cities. In the three years between the establishment of the protectorate in 1911 and the outbreak of World War I in 1914, the European population grew from nearly 10,000 to nearly 50,000, of whom 25,000 were French.

Agriculture (grain, wine, tobacco, and olive oil) was important everywhere in North Africa. There was no industry to speak of, though phosphates were important in Tunisia. In Morocco their presence was known, but it was not until 1914 that the Service des Mines first started prospecting. France controlled foreign trade. Algeria was responsible for two-thirds of all trade from North Africa. Before 1914 Morocco's economy was hardly developed, the value of its foreign trade being only one-sixth that of Algeria.

Algeria had been conquered in order to restore the prestige of the monarchy, Tunisia in order to restore the prestige of the nation. In neither case there had been a grand design. Morocco was a different matter. It was part of a geopolitical concept that had been developed in the 1890s by the *parti colonial*—the French colonial lobby. According to that vision, North Africa had to be turned into a new France on the

other side of the Mediterranean, and French West Africa was to form the hinterland for that.

French West Africa

The French presence in West Africa goes back to 1659, when Saint-Louis was founded, on the mouth of the Senegal River. In the 1850s Senegal became the starting point for French territorial expansion into West Africa. French colonial policy in West Africa was dominated by the military, which often ignored the wishes of and orders from Paris. It aimed at penetrating Africa via the Senegal River, eventually reaching from the Upper Senegal to the Upper Niger. This policy led to a series of wars with local Islamic empires that lasted until the end of the 1890s. In February 1890, Ségou, the capital of the Tukolor Empire, was taken by the French without much difficulty. This broke the power of its ruler and actually put an end to the Tukolor Empire. Meanwhile the French had become entangled in a much more protracted and difficult conflict with the man who would become their most formidable opponent in West Africa: Samory.

Samory (c. 1830–1900) was a born leader with great military and organizational skills, and he built a big empire in West Africa. French expansion brought them into conflict with him. This led to a number of campaigns and battles in the years 1881–1885 that turned out badly for Samory because of the superiority of French firearms. Therefore on 28 March 1886 he concluded a peace and trade treaty, the terms of which included the demarcation of the borders between the French sphere of influence and that of Samory. In May 1891, however, Samory broke with France after a series of border incidents. This marked the beginning of the so-called Seven Years' War against Samory. After a long interlude from 1894 to 1898, the French launched a new campaign in the spring and summer of 1898, and on 29 September Samory was captured. The French governor banished him to Gabon, where he died of pneumonia on 2 June 1900. In the meantime France had also acquired possessions on the Côte d'Ivoire and in Dahomey. After a delimitation of the French and British spheres of

Patriotism is when love of your own people comes first; nationalism, when hate for people other than your own comes first. • **Charles de Gaulle (1890–1970)**

influence, the French became masters of the majority of West Africa.

The French territories in West Africa originally consisted of a number of separate colonies. These were later united to form one large federation, *Afrique Occidentale Française* (AOF), or French West Africa. The total area of the AOF eventually amounted to 4,674,000 square kilometers (in 1919). This made the AOF by far the largest colony in Africa, covering a territory more than eight times that of France itself. With a population of 12 million people, the AOF was the showpiece of French Africa. It was a federation consisting of the former colonies of Senegal, Côte d'Ivoire (Ivory Coast), Dahomey, Guinea, Upper Senegal–Niger (in present-day Mali), Mauritania, and Chad–Niger. The governor-general, who exercised total power over these territories, had his seat in Dakar. The governors of the various regions were subordinate to him. Although local rulers were kept on at first, they were gradually phased out. The kingdom of Abomey, for example, was abolished in 1900 simply on the orders of the governor of Dahomey. It took a long time, however, for the whole of the AOF to be brought under French control. The rain forest regions and the Sahel (semiarid edges of the Sahara) were particularly difficult to subdue. The decisive phase in this process took place between 1908 and 1912. In Mauritania pacification took even longer to accomplish.

Trade in French West Africa consisted mainly of bartering. The trading houses supplied European goods (textiles, hardware, trinkets, as well as weapons and liquor), and exchanged them for African agricultural products (peanuts, palm oil, rubber, and ivory). Trading houses from various European countries were active at first, but trade gradually became the near monopoly of a few large French enterprises. In the Sudan and Senegal these companies came mainly from Bordeaux, those active on the coast of Guinea chiefly from Marseilles. There was relatively large-scale public investment in the AOF, in any case more than in the French Congo. In 1914 the total length of the railway network in use in the AOF was 2,494 kilometers. These lines had been funded primarily by subsidies from France or loans guaranteed by the

colonial government. There was very little mining. French West Africa was therefore of limited economic importance.

French Central Africa: The AEF

After the Berlin Conference of 1884–1885, in which European colonial powers negotiated the future course of central Africa, two Congos came into being: the French Congo and the Congo Free State of the Belgian King Leopold II (1835–1909; reigned 1865–1909). Initially the French Congo comprised various administrative units—Gabon, Congo, Shari, and Chad—which were governed in different ways. In 1906 a federation was established, and in 1908 a governor general was appointed for the territory that in 1910 would be renamed *Afrique Equatoriale Française* (AEF), or French Equatorial Africa. This federation consisted of three colonies: Gabon, Middle Congo, and Ubangi-Shari. Its total area—2,510,000 square kilometers—was slightly more than half that of the AOF. With only 3 million inhabitants, it was sparsely populated and of very limited economic importance.

Madagascar

The interest France took in Madagascar, most of which was ruled at the time by the local Merina kings, was prompted mainly by Catholic missionaries and by the French colonists on Réunion. After some incidents in which French inhabitants were killed, the decision was taken to send a French force to the great island. In December 1894 the navy occupied the harbor of Tamatave and several other ports. A large expeditionary force was raised. On 26 September it reached the capital, which surrendered a few days later. The next day the treaty was signed that made Madagascar a French protectorate. But the protectorate system did not work out well: revolt and anarchy were the result of it. On 20 June 1896, Madagascar was annexed, and in September a governor-general was appointed, in whom all military and civil authority was vested. This governor-general was Joseph Gallieni (1849–1916); his second-in-command was Hubert Lyautey. Together they set about pacifying the island. By the

time Gallieni left the island in 1905, it had largely been brought under French control.

Indochina

The French presence in Indochina went back to Napoleon III's Second Empire, when Cochin China (in present-day southern Vietnam; the region had been ruled by the emperor of Annam) was acquired and Cambodia came under French protection. This was the starting point for a further expansion of French power. During the Second Empire, expeditions had already been undertaken from Cochin China—via the Mekong and the Red River—to the north, in the direction of China. These were resumed after 1870. A fleet was brought together, the Gulf of Tonkin blockaded, and an army of four thousand men was raised. On 18 August 1883, Hue, the capital of Annam, was bombarded and occupied. On 25 August a treaty was concluded, whereby Tonkin was separated from Annam and brought under French rule. Annam itself became a French protectorate. Revolt broke out in Annam in 1885, but it was put down with the capture of the emperor of Annam in 1888. Rebellion in Tonkin was more protracted, lasting twelve years and falling into two phases. In the first phase (1885–1891), the French military presence was very limited, being confined to no more than a few posts and a number of mobile columns deployed to pursue the enemy. In 1892 a new phase began with the arrival of Gallieni. Pacification was now taken in hand systematically, reaching a successful conclusion in 1898. From 1892 to 1896, Gallieni held the reins, and from 1894 he was assisted by Lyautey. These two men are remembered as the greatest generals in French colonial history.

In 1891 the whole of Indochina was placed under the supervision of a governor-general. Subordinate to the governor-general were the lieutenant governor of Cochin China and the *résidents-supérieurs* in the remaining territories, who were charged with the day-to-day running of the government. The remaining power structure of the Annamite monarchy was dismantled. Tonkin was completely separated from

Annam and was administered as a colony rather than as a protectorate.

The last—and largest—of the five territories of French Indochina to be brought under French rule was Laos. The various Laotian principalities had been subjected to the suzerainty of their neighbour countries, with Siam being the most important of them. In 1889 a treaty was signed by France and Siam which recognized French influence in Laos. This treaty however did not bring a definitive solution for the Franco-Siamese rivalry over Laos and in 1893 an armed conflict came into being. By the Treaty of Bangkok (3 October 1893) Siam accepted the French claims on Laos.

Economically and financially, Indochina presented a paradoxical picture. Although the government was rich and the levels of public investment were relatively high, the economic importance of the area was small and French private investment and trading activities remained limited. The reason for the government's wealth was simple: The tax burden on the Indochinese population was high. The consequences of this were predictable: protests and resistance, which in turn, fueled the nationalist movement.

When pacification had been completed, Paul Doumer, who was governor-general from 1897 to 1902, set up a new fiscal system. In place of the old Annamite poll tax and forced labor, direct taxes were introduced, namely, a land tax and a personal tax. The most painful burdens, however, were the government monopolies of opium, liquor, and salt. The salt monopoly in particular encountered a lot of resistance. Administratively, the system was a success, however. There was a budgetary surplus, and the budget of Vietnam even exceeded that of Algeria. The surpluses made it possible to float colonial loans, creating a substantial public debt. Government revenues also made it possible to invest heavily in the infrastructure. Because private capital was not forthcoming, the government offered financial support and developed initiatives itself. The largest project was the construction of the railways.

From World War I to the End of the Empire

With the acquisition of Morocco the French Empire had almost reached its final form, although there was still somewhat more to come. After World War I the colonies of defeated Germany were divided between the victors. Thus France acquired half of Togo and almost all of Cameroon. The Ottoman Empire, also defeated in the war, lost its former territories too: Syria and Lebanon became French mandates.

In the 1920s the French Empire—and Algeria and Indochina in particular—became of increasing economic importance, but like all tropical colonies, the French possessions suffered heavily from the depression of the 1930s. In the same years the French finally acquired a colonial consciousness. They had had an empire for quite some time without being very much aware of it. Now this changed. The great colonial exhibition in Paris of 1931, which colorfully evoked the size and variety of the French Empire, strongly contributed to this awareness.

Thus the 1930s were the heyday of French colonialism. But even in that decade the end of the empire had already become visible. Nationalist movements in the colonies were growing in importance, particularly in Vietnam, where it had begun as early as 1904. The soldiers who returned to Africa from World War I's Western front were also influenced by nationalist ideas. World War II was the shock from which the empire would never recover. During the Japanese occupation of Indochina, the nationalist leader Ho Chi Minh (1890–1969) waged guerrilla warfare against the Japanese. After the war he wanted independence. Negotiations with France broke down, resulting in a war that went badly for France. After a military disaster at Dien Bien Phu in 1954, the French withdrew from Indochina. In 1956 Morocco and Tunisia, and in 1960 all French colonies in Sub-Saharan Africa became independent. The bitter war that had broken out in 1954 in Algeria ended in 1962, with Algeria's independence. It had also brought about regime change in France itself, with

the establishment in 1958 of the Fifth Republic. The French colonial empire was no more.

Frontiers

Throughout civilization frontiers have served as boundaries between strong states and stateless societies, or between populous and sparsely populated areas. Frontiers have been crucial for defense, and for cultural exchange and trade. But the development of frontiers has had devastating effects on indigenous populations residing in them and has resulted in ecological degradation.

The term *frontier* is used to denote the boundary between a society with a strong state structure and a society without a state, or, in some cases, the boundary between highly populated and relatively unpopulated regions. Frontiers have existed since the beginning of civilization and have played an important role in the interactions between different types of societies. Historically, the Roman frontier in western Europe against the Germanic tribes fostered the growth of militarism in Roman society; the vast stretches of Siberia conquered by Cossacks and other Russian pioneers from the late sixteenth century onward led to the creation of a highly centralized state; and the North American frontier from the seventeenth to the nineteenth centuries has, according to some, made the United States unique, different from western European societies.

How interaction across the frontier was regarded depended on which side one occupied. On the one hand, stateless societies have been eager to trade with or raid the more highly structured societies on the other side of the frontier, since highly structured societies tend to be richer in material goods than less complex societies. On the other hand,

although trade and other exchanges were often essential to both sides, structured states generally disdained and feared those on the other side, whom they considered barbarians. On occasion the less highly structured societies have conquered the states across the frontier. For example, in the thirteenth through fifteenth centuries, the Mongols, a frontier people from the north of China, conquered both the Chinese and Arab civilizations, bringing destruction but also creating one of the most extensive land empires of human history, and thereby making possible widespread trade and contacts between civilizations on the Eurasian landmass in ways that had not occurred before. Thus, an Italian merchant such as Marco Polo could travel from one end of the landmass to the other and back, bringing tales of European society to the Mongol court and tales of Asia home to Venice.

Military Considerations

Civilizations tried to protect themselves from marauders from the other side of their frontiers, with uneven success. Attempts at protection brought about some of the most important military engineering works in human history, such as the Great Wall of China, initially built around 200 BCE by the Qin emperor and later elaborated upon, especially during the Ming dynasty (1368–1644). Another famous wall meant to keep out barbarians was Hadrian's Wall, a Roman defense built in Northumberland, Britain, in 122 CE. The Romans built other defensive walls, called *limes*, in the first century CE on the central European frontier. Walls alone were never enough; they had to be supported by forts and, most

Attempts at protecting frontiers fostered important feats of military engineering, such as China's Great Wall.
Photo by Thomas Christensen.

importantly, by alliances with peoples on the other side of the frontier. Although tribal peoples were able occasionally to raid their neighbors across the frontier, usually the armies of those neighboring states were militarily superior. Only when strong states grew weak, as happened to Rome after 200 CE and to China at various points in its history, were tribal peoples able to overcome and conquer them. After the seventeenth century, the development of field artillery gave states the upper hand, and no stateless society was able to conquer a state again. The last victory for tribal peoples was the 1644 Manchu overthrow of the Ming dynasty in China; like the Mongols before them, the victorious Manchu embraced the state structure and established the Qing dynasty (1644–1911/12).

Along most frontiers there lived marginal people who moved between the stateless societies and the states, living at different times in either society. They served as buffers between those on either side and, when mobilized by the states, as troops. In Russia,

the Cossacks, peoples living in the northern regions between the Black and Caspian seas (and later along the Dneiper and Don rivers in western Russia) explored Siberia and served as the Czar's troops from the sixteenth century onward. Although the Russian state made use of them, it also feared them, and they came to have a reputation as unruly rebels. The Cossack Ermak, who initiated the conquest of Siberia, had been a river pirate before working for Ivan the Terrible (1530–1584). Likewise, in the nineteenth century the gauchos of the pampas in Argentina and the *llaneros* of the tropical plains of Venezuela and Colombia served as the soldiers of the patriot forces that liberated the continent from Spanish rule. They were the quintessential tough marginal peoples who, habituated to hard living on the frontiers, were superb soldiers.

Cultural and Economic Exchanges

Although much of the information we have on frontiers relates to defense (for defense preoccupied the

states, and it was the states that wrote the histories), frontiers have also been areas of vital cultural change and important in economic terms. Stateless societies adopted the cultural practices or technologies that suited them (such as ironworking), and on occasion the states adopted elements from the stateless societies (as with the Chinese court's adoption of "barbarian" musical modes or European colonists' adoption of the foodstuffs of the New World, introduced to them by the indigenous peoples). Frontier peoples also often provided labor, either coerced—prisoners of war were turned into slaves or serfs—or voluntary.

The North American Frontier Myth

One of the great frontiers was the one created in North America with the coming of the Europeans. Like the Russian frontier, the North American frontier engendered many myths that provided a sense of national identity. The U.S. historian Frederick Jackson Turner (1861–1932) asserted in 1893 that the United States was defined by its frontier. According to Turner, the frontier inspired and elicited individualism, democratic values, and vigor as the settlers moved westward. In his view, the most valued characteristics of the United States came from the struggle to claim new land from indigenous peoples and adverse conditions. Although a popular and enduring national myth, this analysis has many flaws. In the American South, for example, frontier development went hand in hand with slavery—a fact that does not sit well with the notion of the frontier as a place of democratic values. Nor did Turner's analysis address the moral problem of displacing the land's original inhabitants. By the time Turner wrote his essay, the frontier had effectively closed in the United States, but his analysis nevertheless resonated deeply and maintained a powerful hold on the national consciousness.

Frontiers and Environmental Degradation

Although the development of the North American frontier had calamitous effects on the Native

American populations, it and other frontier development from the late nineteenth century onward have had another devastating effect with long-term consequences: environmental degradation. Ill-conceived farming practices in the Great Plains resulted in the dust bowls of the 1930s; intensive cultivation of cotton along tributaries of the Aral Sea in Central Asia have reduced the sea's volume by 75 percent. Industrial development in Russia's Siberian frontier has resulted in extremely polluted sites, threatened the survival of wildlife, and affected the health of inhabitants. The development of the last great frontier, the Amazon, continues to be plagued by environmental problems, as mining brings with it such ills as mercury contamination, and the establishment of ranches and large-scale agriculture results in erosion and species loss. As with the development of earlier frontiers, it is indigenous populations and the marginal frontier populations that suffer the negative consequences of current frontier development most heavily.

Frontiers vs. Borders

The terms *frontier* and *border* can sometimes be synonymous, but historians make distinctions between them. Frontiers are areas of interpenetration between societies, while borders are established by states to separate their subjects and territories from other political jurisdictions.

Although people often use the terms *frontier*, *boundary*, and *border* interchangeably, and in some forms of usage the terms can be regarded as synonyms, historians have emphasized important distinctions between frontiers and boundaries. Frontiers are, above all, zones of interaction. They can arise as a result of cross-cultural encounters, population movements, and the absence of state authority or an effective monopoly of violence. The historian Leonard Thompson has defined a frontier thusly: "In our usage, a frontier is an area of interpenetration between societies. It contains three elements: a territorial element, a zone or territory as distinct from a boundary line; a human element, comprising peoples of initially separate and distinct societies; and a process element by which relations among such peoples commence, develop, and eventually crystallize. A frontier opens with the first contact between members of these two societies. It closes when a single authority has established political and economic dominance . . ." (Lamar and Thompson 1981, 87).

In contrast, boundaries are established by states to separate their subjects and territories from other political jurisdictions. The political geographer Ladis Kristof defines a boundary as the "outer line of effective control exercised by the central government" (Kristof 1959, 270). Borders are legal and political

infrastructures created by states to maintain boundaries and regulate movement. Frontiers and boundaries have been important factors in global history, but a truly global survey of their impact has not yet been written.

Frontiers

Although the term *frontier* can be traced as far back as medieval Spain, it has most frequently and famously been applied to North American history. For more than a century historians in the United States have debated the "role of the frontier" in U.S. history. In 1893 the U.S. historian Frederick Jackson Turner spoke of "the" frontier as a "meeting point between savagery and civilization," the "edge of free land," and "the line of most rapid and effective Americanization." He argued that in frontiers one could witness in rapid succession various forms of social evolution such as hunting, trading, ranching, farming, and finally manufacturing. Such characteristics of the United States as democracy, individualism, and idealism could, in his opinion, be attributed to the frontier experience. Many of Turner's conclusions have been disputed, disregarded and replaced by more nuanced models of interaction between settlers and indigenous populations in North America, but the frontier still persists in popular imagination and popular culture. Turner himself saw comparative possibilities for analyzing frontier influences beyond North America: "For a moment at the frontier the bonds of custom are broken and unrestraint is triumphant...each frontier did indeed furnish a new field of opportunity, a gate of escape from the bondage of the past." His concept of the frontier has been applied with varying degrees of success to such

Remains of a portion of Hadrian's Wall and an entranceway in Scotland. The wall was meant to keep the Romans from expanding the boundary of their empire further north. Photo by Chris Howell.

diverse areas as Australia, South Africa, Russia, medieval Europe, and the Roman Empire.

In 1952, Walter Prescott Webb, a Texas historian who had previously studied the Great Plains, published a study that attempted to apply the frontier model on a global scale. The discovery of West Indies by Columbus and the ensuing exploration of the Americas, in his opinion, opened up a “Great Frontier” for European expansion. The West, he argued, enjoyed unparalleled access to land and resources, creating an economic boom that lasted for centuries. The closing of the Great Frontier, however, presented a new challenge to the West. With land for settlement no longer available and resources no longer easily accessible, Western society, together with its capitalism, democracy, and individualism, faced the possibility of uncertainty.

The world historian William H. McNeill revisited the notion of the Great Frontier in 1983. He focused on European settler societies in certain areas of the world and evaluated the ways in which frontier conditions transformed the societies and economies created as a result of the migration of Europeans across oceans and across the Eurasian steppe (the

vast, usually level and treeless tracts in southeastern Europe or Asia) after 1500. The Great Frontier was characterized by a dichotomy between freedom and compulsion. In some cases the frontier promoted freedom and equality (the Cossacks, European colonists in North America), whereas in others the availability of land and relative shortage of labor led to enslavement or enserfment of workers. McNeill's work helped to frame frontiers in such a way that no single outcome could be considered characteristic of frontier processes.

Most recently the anthropologist Igor Kopytoff has applied the frontier concept to broad expanses of African history. In various places and periods networks of local frontiers formed a great process in African history. As a result of famines, conflicts, ecological pressures, and entrepreneurial pursuits, individuals and groups took up residence in “no-man's lands” beyond the jurisdiction of established communities. After they were successfully established, they formed a nucleus of a new group, which could serve as a magnet for the disaffected groups and individuals from neighboring societies. Given the right conditions (distance, ecological barriers, inability of existing

Before I built a wall I'd ask to know / What I was walling in or walling out.

• Robert Frost (1874–1963)

societies to extend control), new polities (political organizations) emerged at the margins of existing polities. Some of these new polities eventually became powerful enough to form new polities and absorb their older neighbors. Kopytoff's model effectively distanced frontiers from predetermined outcomes: "The frontier is permissive rather than determinant, it does not create a type of society, but provides an institutional vacuum for the unfolding of social processes" (Kopytoff 1987, 14). Thus, each frontier provides the possibility of generating multiple outcomes.

Comparative frontier studies have gradually abandoned the Eurocentric models promoted by Turner and his students. Historians in the United States still debate Turner's legacy, with some even rejecting the term *frontier* because of its cultural baggage, but many sophisticated studies of cross-cultural interaction, ecological transformation, and settlement owe an intellectual debt to Turner.

Applied on a global scale, the frontier concept provides a lens for examining how the forces of environment, cross-cultural interaction, and adaptation can create new communities and societies. Furthermore, frontiers demonstrate how important processes of change can originate at the margins of existing societies and how peripheries can become new centers.

The Question of Ancient Borders

Although people often consider borders to be characteristically modern, recent research by the Italian historian Mario Liverani has documented their existence in international relations of the ancient Near East. During the late Bronze Age (c. 1550–1200 BCE) interstate relations developed between emerging states in Anatolia (in modern Turkey), Egypt, Mesopotamia, and the lands adjacent to or between those states. Many of the rulers of such ancient states claimed to be universal rulers, but they nonetheless delineated fixed borders of effective control. In the ideology of kingship, the ruler should continuously expand his territory to the ends of the known world. Because the process of expansion would never be complete,

rulers often erected commemorative monuments at the extremities of the territories they had conquered or traversed. Liverani writes: "if we view the border as an elastic perimeter that follows the outward movements of the king, the stela [a stone slab or pillar used for commemorative purposes], which has his name and image inscribed upon it, acts as a substitute for his presence" (2001, 34).

Borders in the ancient Near East were fixed by treaties between two equal parties or between the victor and the vanquished. Existing treaties mention features of the landscape, names of cities, and lists of settlements subject to each ruler. A major question was the distribution of revenues, or who would pay tribute to whom. Treaties also defined penalties for raiding, promoted return of runaways, and included terms of trade. Safe conducts—documents guaranteeing the right to travel across a ruler's territory without bureaucratic hindrance from minor officials—originated in Near Eastern diplomacy to facilitate the movement of representatives of a ruler across foreign territories.

We should not view these ancient boundaries of control, however, as the exact equivalent of modern territorial borders. Rulers were mainly interested in controlling strategic points. Liverani states: "The territory controlled by the state resembles an 'oasis' . . . there is no need for a boundary line, but rather for 'gateways' channels of controlled communication with other states (or other inhabited areas) beyond the depopulated belt" (Liverani 2001, 52). Remote border posts acted as a filter to let desirable persons and things pass on into heart of the state and to keep out undesirables.

Imperial Boundary Maintenance in Eurasia

In global history the Eurasian steppe has been the scene of various attempts by sedentary societies to create artificial barriers to impede the movement of more mobile societies. These barriers required large investments of resources, and in some ways they foreshadowed the functional role of modern borders in

managing and controlling movement. Various states have used physical barriers in attempts to control the mobility of both their subjects and foreign adversaries. As late as the seventeenth century, Russia used the Belgorod Line, an earthen and wooden barrier created to prevent nomadic attacks, to also limit the outward movement of its subject serfs to freedom in areas of the steppe beyond state control.

In the historiography (the writing of history) of western Eurasia, the remnants of Roman military fortifications have long attracted the attention of scholars. European historians were intrigued by the possible function of structures such as Hadrian's Wall, which stretches virtually from sea to sea across Great Britain and once featured three layers of barriers: ditches, walls and watchtowers, and military roads, forts, and mobile patrols. One Roman source explains that the purpose of the wall was "to separate the Romans and barbarians" (Jones 1996, 47). The sixth-century Byzantine historian Procopius could even imagine the wall as a dividing line, beyond which human habitation was literally impossible due to pestilential air. Although boundary maintenance structures have been imagined as zones of extreme exclusion, the evidence points to a much more complex picture.

Because Roman frontier forts and garrisons ringed the diverse edges of the Mediterranean world, historians have tried to make sense of the role of border fortifications in diverse terrains. The military historian Edward Luttwak's *The Grand Strategy of the Roman Empire*, published in 1976, argued that a Roman unified system of defense in depth was developed by the Flavian emperors (second century CE) and subsequent emperors and was applied strategically to the empire's vast frontiers. Historians have debated whether these barriers indicate an aggressive or defensive posture, whether strategic thinking on an empire-wide level can in fact be documented, whether far-flung infrastructures were ad hoc (concerned with a particular end or purpose) local measures or were centrally planned, whether Roman ideology could ever admit a limit to expansion, and whether Greek traditions of building military barrier walls influenced Roman actions. Discussions have centered even on

the meaning of the word *limes*, which some historians have used to describe the frontier defense "system," but which others think referred only to military road networks. Because the "barbarian" invasions played a role in the fall of the Roman Empire in the West, discussions of frontier fortifications have implications for broader questions of imperial decline/transformation. Textual evidence is limited, but hundreds of miles of fortifications and thousands of archaeological sites in Africa, Asia, and Europe have yielded new information. At the very least the Romans seem to have been operating strategically in similar ways in different regions, in some cases setting the agenda, in other cases reacting to circumstances. Although barriers clearly were designed to deal with medium-intensity threats and were supported by intricate systems of garrisons and communication networks, the contemporary sources do not explicitly define the parameters of grand strategy.

Rather than separate Romans from "barbarians," the boundary fortifications often facilitated contact between Romans and their neighbors. The archaeologist Peter Wells has documented the impact of Roman expansion along the Rhine: "The Roman expansion into temperate Europe can be productively viewed as a process that involved interaction between peoples, negotiation with political leaders, and sometimes combat" (Wells 1999, 95).

Archaeology, inscriptions, and texts demonstrate that the lines between Romans and their neighbors were more blurred than previously thought. Many non-Romans were living in Roman territories and employed by the Roman army. Even groups living far beyond the border in an expansive frontier zone were influenced by Roman culture and participated in trade networks. Objects traded hundreds of miles from the farthest Roman forts suggest connections rather than separation.

Historians examining more than two millennia of interaction between China and Inner Asia have faced similar problems of interpretation. Here, too, walls provide visual evidence of ancient divisions, but these walls are subject to varying interpretations. In his classic study *Inner Asian Frontiers* the Asian studies expert Owen Lattimore spoke of the Great Wall of

China as a dividing line ordained by the environment. It roughly approximated an ecological fault line between lands to the south, which were conducive to agriculture, and to the north, which were the domain of pastoral nomadism. For him the Great Wall was a kind of “optimum limit of growth” for the Chinese Empire, but he emphasized that a linear boundary could not be established (Lattimore 1951, 238, 240). He focused attention on the struggle for control of marginal lands and a series of transitional zones between “full Chinese order” and “full steppe order” (Lattimore 1951, 498).

The historian Andrew Waldron has convincingly argued that “there was no single Great Wall in the Chinese past” (Waldron 1988, 69) and that pre-nineteenth-century Chinese observers rarely spoke of a single structure. European notions of a “Great Wall of China” evolved during centuries, influencing modern Chinese perceptions and culminating in the myth (developed during the late nineteenth century) that the “Great Wall” is the only human-made object visible from outer space. Waldron traces how simple earthen fortifications (first mentioned in 656 BCE) emerged, were unified in a system of walls under the Qin dynasty (221–206 BCE), and finally, many centuries later, became identified as an ancient structure ranging for more than 9,000 kilometers. These ancient walls were variously built, abandoned, repaired, and abandoned once again. Furthermore, wall building was only one of many strategies for dealing with the nomads. Furthermore, we can draw no direct correlation between wall building and the weakness of the Chinese state. Finally, the massive brick and stone walls that are commonly visited by tourists near Beijing were built relatively late, during a new period of wall building by the Ming dynasty (1368–1644).

Recent scholars have likewise looked at interactions across the Chinese walls. The walls themselves were never able to enforce a complete dichotomy between the Middle Kingdom (China) and the “outer darkness” beyond its borders. Several studies have demonstrated how nomadic confederacies thrived because of interaction with China. Anthropologist Thomas Barfield has argued that the success of nomadic confederacies depended upon a ruler’s abilities to secure resources

from China. To do this, he might organize raids or act as an intermediary between China and the steppe. Often nomadic confederacies avoided conquering Chinese territory and preferred to use their power to extract resources, subsidies, or access to trade. The historian Sechin Jagchid has argued even that trade was the “essential element that determined whether peace or war existed along China’s northern frontier” and has traced key institutions such as frontier markets, tribute, bestowals (acts of gift giving), and exchanges of brides between Chinese and nomadic rulers (Jagchid and Symons 1989, 1).

The resources necessary for boundary maintenance were enormous, and infrastructures were expensive to maintain. Policies such as diplomacy or trade proved to be cheaper and, in some cases, more effective. Even walls could not stop cross-cultural interaction because populations that appeared to be distinct when viewed from the perspective of the center were in fact often blurred when viewed at the margins.

Borders as a Global Framework

Boundaries and border infrastructures have not necessarily been pervasive in global history. In fact we do not know even how common boundaries were in certain parts of the world before the modern period. Many societies recognized some form of boundaries and created fortifications, but these were not necessarily linear or territorial borders in the modern sense.

The rise of Islam provides an interesting example of boundary conceptualization. Islamic political theory does not seem to have recognized the notion of political boundaries. According to Ralph Brauer, boundaries were noncanonical in Islamic law. Islamic jurists conceptualized the world as divided into two irreconcilable realms: the *Dar al Islam* (land of Islam) and the *Dar al Harb* (land of war). In theory Islam was expected to be ever expanding until the Islamic community was coterminous (having the same or coincident boundaries) with the whole world. Sanction for jihad (holy war) against non-Islamic states makes the boundaries of Islam permanently in a state of flux. Although Islamic statecraft recognizes temporary peace agreements with non-Muslims and

brief, strategic concessions, in Islamic statecraft there was apparently no such thing as a permanent boundary. This unique approach might be explained by the fact that linear boundaries were not practical in the desert nomadic culture that influenced early Islam. The fourteenth-century Arab historian Ibn Khaldun, for example, portrays Islamic states as surrounded by border zones rather than lines. Early Ottoman expansion seemed to confirm the notion that Islamic states should only expand their borders and dictate terms of surrender to their opponents, but eventually expansion stalled and pragmatism set in. After the Treaty of Karlowitz (1699) Ottoman diplomats recognized mutually delineated political borders between Islamic and non-Islamic states, creating a precedent for participation of Muslim countries in the modern international system.

Modern International System of Boundaries

Although various aspects of modern borders have ancient antecedents, the modern international system of territorially conceived sovereign states is usually traced to the Peace of Westphalia, which was concluded in October 1648. The text of the treaty did not specifically deal with the question of borders, but it did establish a principle of territorial inviolability. The treaty recognized its signatories as equal, regardless of size, religious confession, or previous imperial affiliation. It also confirmed each ruler's sovereignty over his or her subjects. By diminishing the power of Catholic Church and the Holy Roman Empire, it set the stage for an international system of states that regulate their affairs through common and mutually acknowledged patterns of diplomacy and international cooperation. This system, with mutually recognized borders and state sovereignty within them, was gradually expanded and applied to various parts of the world.

As the historian Peter Sahlin demonstrated, the territorialization of the state in Europe was a long and tortuous process. Sahlin examined the history of the border between Spain and France in one area of the

Pyrenees Mountains between 1659 and 1868. Even after the two states agreed in principle on partitioning the Cerdanya Valley between them, ecclesiastical, fiscal, seignorial (manorial), and local jurisdictions did not necessarily coincide with state borders. The creation of the border as an institution was often tied to local interests and grievances, which local people used to seek responses and resources from the national capitals. Although notions of "territorial violations" already had emerged during the late eighteenth century, the border was only vaguely demarcated and rarely patrolled. France first attempted to seal off its border in 1822 to prevent an epidemic, and only by 1868 was a well-marked linear boundary established. Sahlin has tried to dispel the notion that borders were imposed from above on unwilling populations.

Not enough detailed studies are available for us to determine whether the Spanish-French example was typical even for Europe. Nonetheless, the rough contours of the emergence of international borders are evident. During the early modern period (sixteenth to eighteenth century) maps became essential to the delineation of political boundaries, and rulers began to define the limits of their territories with more and more precision. Correspondingly, borders began to be delineated with increasing precision. Usually established by bilateral treaties, borders were demarcated in the landscape (most often by marks on rocks, trees, or special boundary markers) by commissioners representing each state in the presence of local witnesses. The general tendency of the eighteenth and early nineteenth centuries was to try to create rational and orderly boundaries (straight lines appeared for the first time on maps) that coincided with existing jurisdictions or natural landmarks such as rivers. Early efforts at migration control, which were not always necessarily enforced at the borders, aimed to limit the entry or exit of certain groups categorized as undesirable: beggars, carriers of communicable diseases, and politically suspect individuals such as spies, traitors, and revolutionaries.

During the second half of the nineteenth century border infrastructures in Europe became more

elaborate. Passports, which originated as diplomatic safe conducts, were not originally indicative of citizenship and were not universally required for international travel until World War I. As states increased their grasp over their territories, more officials were posted along border roads and in border towns. Often border guards and customs agents carried out fiscal and political surveillance of travelers, but they possessed neither the ability nor inclination to inspect every border crosser or to document every entry or exit (exceptions existed, such as Russia, which zealously monitored movement across its borders). During the last decades of the nineteenth century some European countries moved toward controlled entry policies: documenting the entry and exit of each traveler, whether citizen or foreign national. State efforts to regulate movement were largely confined, however, to ports, trains, and main roads. During the last decades of the nineteenth century some countries passed laws distinguishing foreigners from native citizens in order to protect local labor markets from foreign competition.

During the early twentieth century borders became pervasive on a global scale. Virtually the whole globe was parceled into sovereign jurisdictions, whether inhabited or not. Each state became territorially defined, and each government was authorized under international law to determine whom to admit. Passports became required for movement across international borders. Twentieth-century borders were strongly shaped by the activities of the European colonial powers. For example, in their race to claim huge chunks of Africa after the Congress of Berlin during the period 1884–1885, the European colonial powers ignored existing cultural divisions, drew straight lines across formidable features of the landscape, and even laid claim to territories that had never been seen by Europeans. Antarctica is now the only continent that does not have functioning international borders. By international agreement, most states agreed to renounce claims of territorial sovereignty in Antarctica.

During the 1930s states enacted the first attempts to achieve total control over their borders. Extreme boundary maintenance policies (most notably in

Nazi Germany, the USSR, other socialist states, and areas along politically sensitive tracts in other parts of the world) were often instituted for ideological reasons. State efforts to limit unauthorized movement across boundaries were facilitated by two advances in technologies for impeding movement: barbed wire (developed on the U.S. plains to control cattle during the late nineteenth century) and antipersonnel land mines (developed during the U.S. Civil War).

The Soviet border infrastructure, dubbed the “Iron Curtain” during the Cold War, was the earliest and most extensive of these structures. Although the Bolsheviks espoused internationalism, they also embraced borders. Early Soviet boundary maintenance began during the Russian Civil War (1917–1920) when secret police units were given jurisdiction over the internal lines of demarcation between Soviet areas and the various “counterrevolutionary” governments within the boundaries of the old Russian Empire. Fears of encirclement by aggressive capitalist enemies eager to undermine the Soviet state, coupled with economic pressures to stem the flight of specialists and millions of disaffected citizens, led Soviet leaders to solidify border patrols. By around 1930 more than 50,000 kilometers of Soviet borders were being guarded by forty thousand border guards who were assigned to ten border patrol districts. Borders tended to be more heavily patrolled in the west and in densely populated areas in other parts of Eurasia. In those areas patrol density averaged 2.5 men per kilometer of border, but fewer resources were devoted to areas in Asia or the far north that were remote and difficult to cross because of extreme terrains. An expensive and expansive infrastructure utilized patrols by land, air, and sea, networks of local informants, watchtowers, land mines, tens of thousands of miles of tracking strips (areas that were cleared of inhabitants and vegetation and specially maintained to make surveillance possible and footprints visible), thousands of miles of barbed-wire fences and, eventually, electronic signalization systems. Militarily sensitive areas might also be mined to prevent “border violations.” Access to border zones was rigidly controlled, and Soviet citizens could enter these areas only with official permission. As a result of these

measures, unauthorized entry and exit became virtually impossible between the 1950s and 1991. These measures were replicated in Soviet satellite states, most notably in Germany's Berlin Wall (1961–1989).

Although many such extreme borders disappeared with the end of the Cold War, many remained in place after 2000. Such borders continued to be maintained between India and Pakistan, between the two Koreas, in Israel, parts of the former USSR, China, and so forth. Economic migration has spurred the construction of new border infrastructures in certain areas. Administrative barriers to movement (primarily entry visas and residence restrictions) still limit and regulate movement from developing (or “southern,” Third World) countries to industrialized countries. Although the European Union abolished border controls among its member states in 1999, it strengthened its external borders in southern and eastern Europe. In particular, a highly sophisticated border infrastructure (a twenty-first-century Berlin Wall) was created to protect Spanish enclaves in Morocco from mass migration. The U.S.-Mexico border, which was only sporadically patrolled for much of the twentieth century, has become an increasingly complex border infrastructure. During the late 1990s border sectors near major metropolises such as San Diego, California, and El Paso, Texas, were equipped with walls, infrared scopes, underground sensors, and increased mobile and air patrols. By 2004, 9,600 kilometers of U.S. land borders were patrolled by roughly eight thousand officers, a figure that rivals the density of Soviet border patrol deployments during the 1930s. Thus, globalization did not bring about a “world without borders” during the waning years of the twentieth century.

Fur trading played an important economic role in Russia, Alaska, and North America by opening up the frontiers to settlers in the early 1500s. Native Americans exchanged furs for goods like firearms, blankets, and liquor with early European fisherman and settlers, and later with trading companies that sold the furs to luxury clothing manufacturers or to felting industries that made hats.

The fur trade of North America, which came to dominate the trade from Russia (the only other major supplier of furs), transformed the way Native Americans obtained their food and other subsistence needs and made available to them a wide variety of new consumer goods. It also led to the exploration of much of North America by Europeans. The fur trade grew out of the early contact between Native Americans and European fishermen who were netting cod on Newfoundland's Grand Banks off the eastern coast of Canada. Contact at first was haphazard, and only during the late sixteenth century, when the wearing of beaver hats became fashionable, were firms established to deal exclusively in furs.

The first firms to participate in the fur trade were French, and under French rule the trade spread along the St. Lawrence River, through the Great Lakes region, and down the Mississippi River. During the seventeenth century the English developed a trade through Albany, New York. Then, in 1670, a charter was granted by the British Crown to the Hudson's Bay Company, which began operating from posts along the coast of Hudson Bay in Canada. With the British conquest of New France in 1763, the French trade shifted to Scottish merchants operating out of

Montreal. In 1794, the year Jay's Treaty ceded territory from England to the United States, the fur trade along the Mississippi passed to U.S. interests, culminating in the American Fur Company under U.S. fur trader and financier John Jacob Astor. In 1821 the main Canadian participants merged under the name of the Hudson's Bay Company, and for nearly two centuries this merged company continued to trade in furs.

Prior to the rise of the American colonies in the fur trade, Russia was a major supplier of fur pelts to its near neighbors and to western Europe and parts of Asia. Since the Middle Ages Russia had been an exporter of fur via the Baltic and Black Seas. Long an important part of economic activities, pelts effectively acted as currency, being used to pay for a range of goods or services. With the opening up of Siberia from the sixteenth century, Russia gained access to a rich variety of pelts such as that of the Arctic fox, sable, lynx, and sea otter. In pursuit of animals such as the sea otter, Russian traders ventured into Alaskan North America. The fur harvest from Siberia, particularly the sable, enabled Russia to become the world's largest supplier of fur from the seventeenth century and well into the nineteenth century.

The fur trade was based on pelts that were destined either for the luxury clothing market or for the felting industries, of which hatting was the most important. Hats for centuries were a mandatory part of everyday dress for both men and women, and, although styles changed, the material from which hats were made—felt made from wool—remained the same. The wool came from various animals, but beginning in the sixteenth century beaver wool hats became increasingly popular, eventually dominating the market.

Fur trade with Native Americans led Europeans to explore and settle much of North America.

In Russia the felting industry was based on the European beaver (*Castor fiber*), but by the end of the seventeenth century Russian supplies were declining. Coincident with the decline was the emergence of a North American trade. The pelts of North American beaver (*Castor canadensis*) were classified as either parchment or coat. Parchment pelts were from freshly caught beaver, whose skins were simply dried before being presented for trade. Coat pelts had been worn by Native Americans for a year or more. By the middle of the seventeenth century felt makers were combining parchment and coat pelts to produce top-quality felt for the hat market.

The records of the Hudson's Bay Company allow us to see a clear picture of what items Native Americans were buying with the beaver pelts and other skins that they brought to trading posts. The items can be categorized by use. The producer goods category was dominated by firearms, including guns, shot, and powder. Native Americans traded for guns of different lengths. The 1-meter gun was used mainly for waterfowl and for game in heavily forested areas where game could be shot at close range. The 1.2-meter gun was more accurate and suitable for open spaces. Kettles and blankets were the main items in the household goods category. Luxury goods can be divided into two broad categories: (1) tobacco and alcohol and (2) other luxuries, dominated by cloth. The breakdown of categories varied by trading post

and through time. In 1740 at York Factory, the largest of the Hudson's Bay Company posts, the distribution in terms of value was producer goods, 44 percent; household goods, 9 percent; alcohol and tobacco, 24 percent; and other luxuries, 23 percent.

Like many Europeans and most American colonists, Native Americans were taking part in the consumer revolution of the eighteenth century. In addition to consuming necessities, they were consuming a remarkable variety of luxury products. Cloth, including baize, duffel, flannel, and gartering, was by far the largest class of luxury products, but Native Americans also purchased beads, combs, looking glasses, rings, shirts, and the pigment vermillion.

During the 1720s the price of furs began to rise in response to an increasing demand for beaver hats in Europe. The higher price in turn led to greater fur harvests. Thus, although some contemporaries described Native Americans as "lazy and improvident," Native Americans seized the opportunity provided to them by the strong fur market by increasing their effort in the commercial sector. The result was higher living standards, but also a use of European technology that permanently changed many aspects of Native American society.

Gaia Theory

The Gaia theory holds that Earth's physical and biological processes are inextricably linked to form a self-regulating system that maintains its own habitability. The theory asserts that living organisms and their inorganic surroundings have evolved together as a single living system that greatly affects the conditions of Earth's surface. The theory is often described in terms of Earth acting as a single organism.

In 1969 the British scientist James Lovelock postulated that life on Earth regulates the composition of the atmosphere to keep the planet habitable. The novelist William Golding, Lovelock's friend and neighbor, suggested Lovelock call the hypothesis Gaia, after the Greek Earth goddess. Although in its early exposition and in the popular press the Gaia hypothesis was understood as saying Earth itself was a living organism, the theory as Lovelock came to articulate it said rather that Earth acts like a living organism, with its living and nonliving components acting in concert to create an environment that continues to be suitable for life.

Development of the Gaia Hypothesis

The idea that life is more than a passenger on Earth dates back to the work of scholars and researchers in a number of disciplines: the Scottish geologist James Hutton (1726–1797) and was held by the British biologist T. H. Huxley, the animal physiologist Alfred Redfield, the aquatic ecologist G. Evelyn Hutchinson, and the geologist Vladimir Vernadsky. In 1924 Alfred Lotka—a U.S. chemist, ecologist, mathematician, and demographer—first proposed the radical notion that

life and the material environment evolved together as a system, but few took him seriously.

In the late 1960s, as part of its search for life on Mars, the National Aeronautics and Space Administration (NASA) gathered information on the composition of planetary atmospheres. Lovelock, then a NASA consultant, noted that Venus and Mars both had atmospheres dominated by carbon dioxide and close to chemical equilibrium. In contrast, gases made by living organisms dominate the atmosphere, which, despite being far from chemical equilibrium, is stable in the long term. Lovelock realized that such stability required a regulator and, since the atmosphere was mainly a biological product, proposed that Earth's collective life forms played this role.

In 1971 he began collaboration with the eminent biologist Lynn Margulis, who brought her extensive knowledge of Earth's microorganisms and added flesh to what was otherwise a chemical hypothesis based on atmospheric evidence.

Criticism and Refinement of the Gaia Hypothesis

Lovelock and Margulis's joint work brought strong criticism, mainly from other biologists. W. Ford Doolittle and Richard Dawkins, two vocal critics, stated that there was no way for living organisms to regulate anything beyond their individual selves. Some scientists in particular were critical of the hypothesis for being teleological, or assuming that all things have a predetermined purpose. Lovelock responded: "Neither Lynn Margulis nor I have ever proposed a teleological hypothesis" (1990, 100). Doolittle argued that there was nothing in the genome

of individual organisms to provide the feedback mechanisms Gaia Theory proposed. Dawkins has argued that organisms cannot act in concert, as this would require foresight and planning. Stephen Jay Gould, the renowned U.S. paleontologist and evolutionary biologist, wanted to know the mechanisms by which self-regulating homeostasis is possible. This criticism was in the best traditions of science and required a proper response.

In 1981 Lovelock answered the critics by creating the numerical model Daisyworld, an imaginary planet on which there were two species of plant, one light colored and the other dark colored. The planet was warmed by a star that, like Earth's sun, grew hotter as time passed. When the star was cooler, each dark-colored daisy warmed itself by absorbing sunlight, until dark daisies predominated and warmed the planet; as the star grew hotter, each pale-colored daisy, by reflecting sunlight, kept itself and the planet cooler. The competition for space by the two daisy species kept the planet's temperature constant, thus sustaining a habitable condition despite changes in the heat output of the star. The model showed that even without regulating anything other than themselves, organisms and their environment evolve together as a powerful self-regulating system. This demonstration, along with successful predictions of mechanisms for the regulation of the Earth's climate and chemistry, put Gaia on a firm theoretical basis, which was strengthened by a further suite of models from the ecologists Tim Lenton (in 1998) and Stephan Harding (in 1999).

The Heart of Gaia

Gaia views Earth's surface environment as a self-regulating system composed of all organisms, the atmosphere, oceans, and crustal rocks, which sustains conditions favorable for life. It sees the evolution of life and the evolution of Earth's surface and atmosphere as a single process, not separate processes, as taught in biology and geology. Organisms evolve by a process of natural selection, but in Gaia, they do not merely adapt to the environment, they change it. Humans, clearly, are changing the atmosphere, the

climate, and the land surfaces, but other organisms, mostly microscopic, have in the past made changes that were even more drastic. The appearance of oxygen in the air two billion years ago is but one of them. Gaia stands to Darwinism somewhat as relativity theory stands to Newtonian physics. It is no contradiction of Darwin's great vision but an extension of it.

What use is Gaia? It has been a fruitful source of new research and an inspiration for environmentalists. It led to the discovery of the natural compounds dimethyl sulfide and methyl iodide, which transfer the essential elements sulfur and iodine from the oceans to the land. It showed how life in the soil and on the rocks increases the rate of removal of carbon dioxide from the air and so regulates both the levels of carbon dioxide and, consequently, climate. Its most daring prediction stated in 1987 by Robert Charlson, Lovelock, Meinrat Andreae, and Stephen Warren, was that the microscopic algae of the oceans are linked by their emission of a gas, dimethyl sulfide, with the clouds and with the climate. As Earth gets hotter, the theory says, these algae release more dimethyl sulfide into the atmosphere, which increases Earth's cloud cover, which in turn cools the Earth: without clouds, the earth would be hotter by 10–20°C. This idea is crucial to the proper understanding of climate change. The authors received the Norbert Gerbier Prize and medal from The World Meteorological Office for this theory in 1988. Ten years later hundreds of scientists worldwide were studying the links between ocean algae, atmospheric chemistry, clouds, and climate. Climatologists and even physiologists have used Daisyworld in their research. Over the years, Gaia has changed the way scientists think. There is no better example of this change than the Amsterdam Declaration of 2001. A conference of environmental scientists in 2001 issued the declaration, which had as its first bullet point: "The Earth System behaves as a single, self-regulating system comprised of physical, chemical, biological and human components" (Open Science Conference 2001). Although not yet a full statement of Gaia theory, it a substantial advance on the separated view of earth and life sciences that went before.

In recent years, the Gaia theory has become part of general discussion and popular journalism, especially in relation to global climate change. Its subject, the complex interdependencies of planetary life, is part of the academic curriculum under the name “Earth Systems Science.”

The Revenge of Gaia

In a 2006 book, Lovelock made the argument that environmental degradation and climate change are testing Gaia’s capacity to self-regulate and maintain Earth’s habitability. He believes that it is already too late to avoid significant climate change, thus rendering large portions of our planet much less hospitable for humans. Sustainable development and renewable energy are two hundred years too late to be of much help; it is now time to direct greater efforts towards adaptation. Lovelock is an advocate of nuclear power as a short-term solution for maintaining energy demands, but other clean alternative energy sources are thought to be too little too late. Given the range of environmental stresses, he claims that human civilization will find it difficult to survive as is, with the human population experiencing significant decline during the next hundred years. Lovelock claims that Gaia’s self-regulation is likely to prevent any catastrophic wipeout of life on Earth, but the present course of action is unsustainable, and there will be changes to life on Earth one way or the other.

Galileo Galilei

(1564–1642)

ITALIAN PHYSICIST, MATHEMATICIAN, AND ASTRONOMER

Galileo Galilei (1564–1642) is considered the father of modern experimental science. He pioneered dynamics as an exact science of motion, and through the use of the telescope he demonstrated the validity of the Copernican thesis in the face of denial from Aristotelian academics and Roman Catholic theologians.

Galileo was born in Pisa 15 February 1564, the first of the six children of Vincenzo Galilei, a Florentine merchant and part-time musician. At the age of eleven he was sent to the Camaldolese School in Vallombrosa, and except for his father's opposition he would have become a monk. In 1581 he entered the University of Pisa to pursue a medical degree, but he soon developed a far greater interest in mathematics. With his father's reluctant consent, he abandoned medicine. Leaving the university without a degree, he led an impecunious existence from 1585 to 1589, scraping together teaching assignments in mathematics. During these years he published his first book, *The Little Balance*, inspired by his study of the mathematician Archimedes. It described a hydrostatic balance he had invented to measure the specific gravity of objects.

In 1589, with the recommendation of German Jesuit mathematician Christopher Clavius and fame achieved through lectures at the Florentine Academy, Galileo obtained an appointment at the University of Pisa, where for the next three years he taught mathematics based on the prevailing Aristotelian and Ptolemaic beliefs. In 1592 Galileo secured a more prestigious appointment at the University of Padua, in the Republic of Venice. His eighteen years at Padua, where he taught Euclid's geometry and Ptolemaic astronomy,

were the happiest of his life. During ten of these years, he had a relationship with a Venetian woman, with whom he had three children, a boy and two girls.

Galileo began investigating the Copernican theory in the early 1590s. In a letter to Johannes Kepler in 1597 he said that he had been a believer in Copernicanism for many years, but fear of ridicule prevented him from openly expressing his views. However, in 1604, when a new star appeared, Galileo began lecturing against Aristotle's astronomy. About the same time, he resumed an earlier study on motion, and using inclined planes, concluded that objects fell at the same speed regardless of weight.

In 1609 Galileo perfected a telescope that had been invented by a Dutch optician and used it to point out the fallacy of the geocentric theory. In his first major scientific publication, *The Starry Messenger* (1610), written in Italian instead of the traditional Latin, he described the lunar mountains, the Milky Way, and the satellites of Jupiter. To flatter Cosimo II, Grand Duke of Tuscany, Galileo dedicated the book to him, in the hope that a major appointment in Florence would follow. He was not disappointed: Cosimo named him "Chief Mathematician and Philosopher." In 1611 Galileo visited Rome, where the Academy of Lynxes, composed of the scientific elite, invited him to become a member, and the Collegio Romano honored him with a dinner.

Shortly after publishing in 1612–1613 his *Discourse on Falling Bodies* and *Letters on Sunspots*, Galileo entered the growing debate on the relationship between the Copernican or heliocentric thesis and the Scriptures, which supported the Ptolemaic, geocentric theory. In *Letter to the Grand Duchess Christina* (mother of Cosimo II) Galileo stated that

In questions of science, the authority of a thousand is not worth that humble reasoning of a single individual. • Galileo Galilei (1564–1642)

Giusto Sustermans, *Portrait of Galileo Galilei* (c. 1639). Galileo fostered an intellectual revolution that provided the basis for modern science. National Maritime Museum, London.

a figurative interpretation of the Scriptures was necessary because physical reality demonstrated that the sun was the center of the universe. Galileo was entering the theological domain at a time when the Counter-Reformation was at its height and the reigning pope, Paul V (papacy 1605–1621), was hostile to new ideas.

In 1616 the Holy Office (the Inquisition) unequivocally condemned the Copernican theory. Cardinal Robert Bellarmine, the pope's Jesuit theologian and an adviser to the Holy Office, was delegated to inform Galileo in person that he was forbidden to teach or defend Copernicanism either orally or in writing. But as Galileo seems to have understood, there could be a discussion of Copernicanism as a mathematical construct, but not as a philosophical truth. Accordingly Galileo carried on an extensive correspondence on this subject with his supporters throughout Europe.

His daughter, Sister Marie Celeste, who lived in nearby Arcetri, was very supportive and became a major presence in his life.

In 1623 Cardinal Maffeo Barberini, an old friend of Galileo's and a noted patron of the arts, was elected pope, taking the name of Urban VIII (papacy 1623–1644). Barberini as pope was far less receptive to Copernicanism than he had been as cardinal. In his audiences with Galileo, Urban clearly stated that God was omnipotent and that to speak of Copernicanism as other than hypothetical was to deny divine omnipotence.

Between 1624 and 1630 Galileo wrote the book that would lead to his condemnation by the Holy Office, *Dialogue Concerning the Two Chief Systems of the World: Ptolemaic and Copernican*. Published in Florence in 1632, the *Dialogue* represents Galileo as the epitome of the Renaissance man, reflecting as it does his ideas as an astronomer, physicist, and humanist. The book took the form of a discussion among three philosophers, one who ably defended Copernicanism, another who acted as a facilitator, and the third who ineptly supported the Ptolemaic thesis. Written in Italian in a popular style, the book speedily attracted a wide readership. The Holy Office ordered Galileo to appear in Rome on "suspicion of heresy." His trial, which began April 1633, ended 22 June 1633 with the Holy Office judging him guilty of the "suspicion of heresy." The condemnation was based primarily on his failure to abide by the Holy Office's injunction of 1616. For reasons that remain unclear, Galileo signed an abjuration. He was sentenced to imprisonment at the pleasure of the Holy Office and to the recitation of the penitential psalms once a week for three years. The sentence was subsequently commuted to house arrest in Arcetri.

Galileo spent the rest of his life in relative seclusion, beset by poor health and blindness. Nevertheless, he managed to have published in Holland in 1638 his *Discourses and Mathematical Demonstrations Concerning the Two New Sciences*, in which he developed his ideas on the acceleration of bodies in free fall. He died 8 January 1642 and was buried in the Church of Santa Croce.

In 1979 Pope John Paul II reopened the case of Galileo. In 1992, on the basis of the report of the investigating commission, he declared that the theologians had been mistaken in condemning Galileo. Thus nearly four hundred years after his condemnation, Galileo was vindicated. In the interval he had affected an intellectual revolution that provided the basis for modern science.

Games and Play

Cultural anthropologists in the twenty-first century still rely on a 1959 definition of *games* as recreational activities that are organized and follow agreed-upon rules of play, involve competition with two or more sides, and use criteria for determining who wins. Games involving strategy, chance, and physical prowess remain popular, but electronics and computers have affected the social aspects of games and play.

Games are universal, or very nearly so, in the cultural inventories of known societies, past and present. In their classic article “Games in Culture,” the anthropologists John M. Roberts, Malcolm J. Arth, and John J. Bush (Roberts et al. 1959, 597) defined games as recreational activities “characterized by: (1) organized play, (2) competition, (3) two or more sides, (4) criteria for determining the winner, and (5) agreed-upon rules.” This definition has been particularly influential in anthropology and in the cross-cultural study of games even though it excludes some activities that are commonly referred to as games, including mother-infant activities such as patty-cake, or play activities such as top spinning or making string figures. Roberts and his colleagues referred to such noncompetitive play activities as “amusements.” Roberts and his colleagues also provided an extremely useful classification system for games. This system is based on the factor that is most critical in determining who wins and who loses. They indicated that:

Some outcomes are determined primarily by the physical abilities of the players, some by a series of moves, each of which represents a player’s choice among alternatives, and others either by non-rational guesses

or by reliance on the operation of some mechanical chance device, such as a die; some are determined by combinations of these patterns. All of these ways of determining outcomes are widely distributed among the societies of the world, and it is therefore possible to offer the following general classification of games: (1) physical skill, (2) strategy, and (3) chance. (Roberts et al. 1959, 597)

While others have developed alternate definitions of games and game classification systems, none of these has proven to be particularly useful in cross-cultural research on games and cultural correlates of game types.

The Origins and Evolution of Games

Archeologists and antiquarians have found numerous examples and large varieties of ancient artifacts of game play, such as balls, hoops, marbles, dice, game boards, board game pieces, and playing cards, in sites around the world. Possibly the earliest known game board with pieces was found in an excavation of a predynastic cemetery at El-Mahasna in Upper Egypt in 1909. Alquerque, the ancestor of draughts (checkers in the United States) was played as early as 600 BCE in Egypt.

Early Athletic Games

The development of sporting games, including track and field, wrestling, boxing, and archery, among the ancient Greeks and Romans is well known from archaeological, artistic, and narrative sources. Various forms of art, such as painting and sculpture, from around the world often depict game play. The Greek

Playing Games in December. This drawing from the early Edo period (1600–1867), part of a scroll that presented a month-by-month account of annual events and seasonal plays in Kyoto, shows children playing ball. World Digital Library.

historian Herodotus (fifth century BCE) described games and other pastimes in Lydia (in the west of present-day Turkey) and Egypt while the Roman historian Tacitus (55–120 CE) described dice games as played among Germanic tribes.

The Mesoamerican ball game is one of the best-known ancient games of physical skill. The game and its play are depicted artistically in frescoes, stone carvings, on painted pottery, and in clay figurines of players found in Mexico and Central America. The oldest known ball court, at the archeological site of Paso de la Armada in the state of Chiapas in western Mexico, dates to approximately 1400 BCE. The ball court at Chichén Itzá, the largest in Mesoamerica, was built between 900 and 1100 CE. Simplified versions of the game are still played in northwestern Mexico, principally in the states of Sinaloa, Sonora, and Durango.

Early Games of Strategy

While the precise origins of games of strategy (such as chess or *wei qi* in China; also known as *pa-dok* in Korea and Go in Japan and the West) are either unknown or contested, some aspects of their histories are relatively clear. *Wei qi* means “surrounding game” or “surrounding chess” and has as its goal the capture of territory on the playing board by the placement of markers. While some claim that the game was invented in China more than 4,000 years ago, others suggest that the game originated in Central Asia and diffused through Nepal and Tibet to China. The game is mentioned in the writings of the philosopher Mencius from around 400 BCE, and writings specifically about it date to the Tang dynasty (618–907). *Wei qi*

diffused to Japan in 754 as a gift from the emperor of China to the emperor of Japan.

Chess probably is a descendant of *shaturanga*, a four-player game from India that involved battle between armies that included infantry, cavalry, elephants, and boats, commanded by a raja (king). In a later version, called *shatranj*, the four armies were collapsed to two, much like modern chess. *Shatranj* diffused to Persia from India in the sixth century and reached the Arab kingdoms, Greece, and Medina by about 650. It probably was brought to Europe during the Crusades and became popular in southern Europe by the end of the fifteenth century. Thereafter it rapidly spread throughout the continent.

Mancala (also called *wari* or variants thereof), the third major game of pure strategy found in the preindustrial world, is widespread in Africa. It might have evolved there from an accounting system that used boards similar to those used in the game. *Mancala* boards carved into temple roofs in Memphis, Thebes, and Luxor indicate that the game existed in Egypt prior to 1400 BCE.

Early Games of Chance

Games of chance are based either on the use of a randomization device, such as a die, shuffled playing cards or a roulette wheel, or on non-rational guessing. Early dice included “knucklebones” (usually bones from the ankles of sheep or pigs) that were marked on several sides, but numerous other materials, including antler, pebbles, walnut shells, peach or plum stones, pottery disks, walrus ivory, and beaver or woodchuck teeth, were used as well. Greek and Roman dice were most often made of bone or ivory

A Mesoamerican ball court at Uxmal, in the Yucatan. Simplified versions of this ancient game of skill are still popular in northwestern Mexico.

but amber, marble, porcelain, and other materials were also used. Cubical dice are common, but dice of pyramidal, rectangular, pentahedral, and octahedral shapes also existed.

Playing cards were probably invented in China, perhaps as early as 1000, and may have been based on Chinese dominoes, a game played more like card games than the positional form of modern dominoes. From China, playing cards apparently diffused westward, arriving in Egypt by the twelfth or thirteenth century and Europe by the 1570s. Card games arrived in England around 1520, and the oldest surviving deck of cards from England dates to about 1590. Ordinances directed at regulating card-game playing passed in various parts of Europe in the late fourteenth century indicate both their rapid spread and the alarm that their appearance created among civil and ecclesiastical authorities. The primary concern

with cards, as well as dice, was with their use in gambling games, and prohibitions aimed at gambling have waxed and waned since the end of the fourteenth century. For example, Napoleon legalized casinos in France in 1806, but they were outlawed in 1837. In the American colonies, the Puritans of New England and the Quakers in Pennsylvania generally prohibited gambling, while areas colonized by other English settlers usually viewed it as a harmless pastime. Now, gambling is common worldwide except in those areas where cultural prohibitions still hold sway, such as in Muslim societies and most of China.

Guessing games of chance are also common worldwide. Native North Americans played numerous versions of the moccasin game, for example, in which the object was to guess the location of objects hidden under moccasins. “Rock, paper, scissors” is a modern example of a guessing game.

It should be noted that children at play are not playing about; their games should be seen as their most serious-minded activity. • Michel de Montaigne (1533–1592)

Games as Models

Roberts and his colleagues claimed that games model important real-world activities with greater or lesser degrees of verisimilitude. Chess, for example, is transparently a game of war between two armies, replete with ranks. *Wei qi* is more abstract but still a game of war. Risk is a relatively recent (first published in 1959) war game played on a stylized world map that, unlike chess and *wei qi*, involves chance as well as strategy. While there is no evidence to indicate that board games, such as chess or *wei qi*, were used for training purposes, other competitive events, including the knightly tournaments in medieval Europe and the Afghan horsemanship game, *buzkashi*, provided excellent training for warfare. Monopoly, a model of real estate transactions that also involves strategy and chance, became a popular board game during the Great Depression of the 1930s even though an all but identical game had been patented in the United States in 1903.

Games of chance are commonly held to be models of divination designed to seek supernatural guidance about, or assistance in dealing with, the unpredictable forces of nature that govern human existence. In his monograph *Chess and Playing Cards*, Stuart Culin, the great America game ethnographer, claimed that dice developed from efforts to divine the future by the throwing of arrows (or sticks, straws, or reeds) on the ground and interpreting the result while reciting magical incantations. The “casting of lots,” mentioned in the Bible, was a form of divination based on the interpretation of thrown sticks. Craps players around the world commonly recite “prayers,” saying things such as “Come on, seven!” or “Baby needs a new pair of shoes,” or put their essence on the dice by rubbing them between their hands or blowing on them in the hope of controlling the outcome of the game.

Games of physical skill commonly model either warfare or hunting. Examples include ancient sports such as wrestling, boxing, and spear or javelin throwing as well as the activities of medieval tournaments and fairs, such as jousting, the melee, and competitions

with bows and arrows. Modern sports such as soccer, rugby, and American football bring two opposing armies onto a field of battle while target shooting and trap shooting model hunting. Soccer, or association football, is the world’s most popular participatory and spectator sport. While the modern version was born in nineteenth-century Britain, precursors were played as early as the eighth century. Often known as “mob football,” these games involved an indeterminate number of players (sometimes whole villages pitted against each other), and rules were vague. The origins of mob football are uncertain but its play was associated with Shrove Tuesday. This game modeled combat closely enough to include numerous injuries and often fatalities. According to an ancient document from Workington, England, Shrovetide football players could use any means other than murder and manslaughter to get the ball to the goal. Because of the violence that it engendered, Edward II banned Shrovetide football in 1314, but it is still played in some areas, such as Ashbourne in Derbyshire.

Recent Developments in Games

New games in traditional formats are continually being developed and marketed by game manufacturers but the most radical development in the recent history of games is their mating to the computer. In 1971, Atari marketed the first commercially successful arcade video game, Pong, a two-person game in which an electronic ball was batted back and forth on a video screen by two paddles controlled by the players. Other arcade games such as Tank (1974), Asteroids (1978), and Pac-Man (1980) soon followed. Odyssey, marketed by Magnavox in 1972, was the first home video game. In 1975, Atari introduced a home version of Pong, and dedicated video game consoles from other companies were on the market soon after. Arcade games were introduced to personal computers in the late 1970s.

Contests between computers (and programs) and master players for classic games such as chess and *wei qi* have captured public interest in recent years. In 1997, an IBM computer named Deep Blue defeated

Chinese men gamble on a cricket fight in the late nineteenth century. Gambling, a component of games and sports in many cultures, dates back thousands of years.

reigning world chess champion, Gary Kasparov, two games to one (with three draws), and chess programs for personal computers can now play very strong games. However, to date, no computer has been able to defeat good human players at *wei qi*.

The Future of Games

New games are continually being invented, while older ones may either be modified or disappear. Watching others play games—spectatorship—is growing, as well. While games of physical skill, such as soccer, baseball, or tennis, draw the most spectators, championships in games of strategy, such as chess, and games of strategy with chance, such as poker, attract many viewers as well. The first casino (from the Italian word “casini,” meaning “little house”) opened in Venice in 1626, but the Monte Carlo casino in Monaco quickly became the world’s most glamorous gambling establishment after its opening in 1863. Each of the thirteen American colonies established lotteries and proceeds aided various public works,

including the establishment of libraries, churches, and universities such as Harvard, Yale, and Princeton, but all forms of gambling were illegal in the United States by 1910. The state of Nevada again legalized gambling in 1931 and the first state lottery was established by New Hampshire in 1963. As of 2009 only two states (Hawaii and Utah) do not have some form of state authorized gambling. The legalization of gambling in much of the world has led to increased participation in games of strategy with chance (such as blackjack, poker, baccarat) and games of pure chance (such as craps, roulette, and lotteries). Casino gaming and lotteries, while providing governments with a new source of revenue, outlets for recreational gamblers, and economic development in areas supported by casinos, also have negative aspects. Gambling addictions are now more common, and the need for policing, access roads, parking, and waste disposal strains local resources. So, while some forms of game playing, such as card games in the home, may be declining because the social gatherings that supported them in the past are themselves declining,

more people are participating in and watching games being played outside the home, and that trend is likely to continue in the future.

While traditional board games and card games may be waning in popularity, computer-based home video games, as well as online games, constitute a huge growth industry and one of the most rapidly expanding forms of entertainment worldwide. (A recent survey indicates that young people in the eight-to-eighteen-year-old range spend an average of 7.38 hours per day, or nearly 53 hours per week, exposed to “entertainment media” including television, music/audio, computers, video games, print, and movies—a significant number of hours that limits other forms of play.) Home use of video games, as well as the increased popularity of Internet game parlors, has led to a steep decline in the popularity of arcades and arcade games. As video and Internet games are most often played alone, either against the game program or distant opponents, they have resulted in less social play than takes place in traditional card or board games and even in arcade video games. Whether such games model the real world of today, as Roberts and his colleagues suggested in the late 1950s, is a question worth pondering.

Gandhi, Mohandas

(1869–1948)

LEADER OF INDEPENDENCE MOVEMENT IN INDIA

Gandhi's significance as a twentieth-century philosopher, pilgrim, world leader, and writer lies in his uncompromising reliance on ahimsa—the Hindi and Buddhist doctrine of nonviolence and restraint from harming all forms of life—as a moral force for reforming and transforming unjust established authority.

Mohandas Gandhi (1869–1948) mobilized the largest nonviolent mass movement known in world history under the banner of *satyagraha*—the active pursuit of truth through love and nonviolence (ahimsa). Gandhi's ideas of truth and justice have contributed immensely to the development of moral and political thought, and his demonstrations of the positive and revolutionary power of nonviolence has had a worldwide impact. His support for nonviolent campaigns dedicated to social and political change around the world gave a sense of power to the powerless and of hope to the hopeless.

Although Gandhi was a prolific and inspirational author whose writings gave guidance to thousands of people around the world, as well as the founder of many ashrams (spiritual retreats) and communal settlements, his life was his biggest message. He is regarded as a mahatma, or great soul, and lived a life of simplicity, nonpossession, celibacy, truth, and nonviolence.

Mohandas Gandhi was born to Putlibai and Karamchand Gandhi on 2 October 1869, in the city of Porbandar, Gujarat, in western India. His father was the prime minister of Porbandar. At thirteen, Mohandas was married to Kasturbai, also thirteen, and in 1888 sent to Britain for higher education in the field of law. Unable to secure a job on his return to

India, Gandhi sailed to South Africa in 1893. There he discovered the oppressive and unjust policies of the British when he was thrown off the train for having a first class train ticket and sitting next to white citizens of the Empire. This was a transforming event in Gandhi's life. A South Africa rife with racial discrimination against colored people became the laboratory for Gandhi's initial experiments with *satyagraha*. Later Gandhi built on these experiments to launch mass *satyagraha* movements during India's struggle for freedom from British rule.

On his return to India in 1915, he became a “pilgrim of truth,” uncovering the roots of mass poverty and unrest over the next five years, and in 1920 he assumed the leadership of the Indian National Congress, the body officially pursuing the struggle for India's independence from the British. Gandhi led several mass campaigns of nonviolent noncooperation and civil disobedience against British rule, and India gained its independence in 1947.

But for Gandhi, national self-government, or *swaraj*, meant more than just independence. To him it meant peoples' total moral authority over themselves so as to require no external coercion. Therefore, Gandhi became an active social reformer, crusading against the Indian caste system, the exploitation of women, and cruelty to animals.

Gandhi's radical insistence on the oneness of human beings, and his persistent efforts to keep Indian Hindus and Muslims united, set him in opposition to fundamentalist Hindus. Earlier attempts on his life had failed, but on 30 January 1948, he was shot during his prayer meeting at the Birla House in New Delhi by a Hindu nationalist, Nathuram Godse. Although Gandhi's assassination appears ironical to some, for

It is unwise to be too sure of one's own wisdom. It is healthy to be reminded that the strongest might weaken and the wisest might err. • **Mohandas Gandhi (1869–1948)**

Mohandas Gandhi, the leader of India's independence movement, was a proponent of peaceful resistance.

others it became a symbol of his fearless dedication to the principles of truth and nonviolence.

While Gandhi's nonviolent philosophy and actions evolved in response to larger social and political problems he personally experienced, he records in his autobiography three major influences on his life and thought: the religion of Jainism, with its core principle of nonviolence; *Unto This Last*, an 1860 collection of essays critiquing classical economics by the British writer John Ruskin; and Leo Tolstoy's treatise on Christian nonviolence, *The Kingdom of God is Within You*.

Gandhi tirelessly endeavored to understand the roots of political and social problems he confronted and to devise means to address them effectively but nonviolently. He felt that violence resulted from poverty, injustice, lack of self-discipline, selfishness, and

ill will. In his seminal work, *Hind Swaraj*, Gandhi offers an enduring solution to these problems in his vision of a civilization that encourages love, truthfulness, social service, equality, and cooperation. Gandhi's ideal society discourages politics without principle, wealth without work, commerce without morality, education without character, pleasure without consciousness, science without humanity, and worship without sacrifice.

Gay and Lesbian Rights Movement

Tolerance of (and attitudes about) gay and lesbian behavior varied throughout history as religious proscription gave way to punitive civil laws and “enlightenment” made homosexuality a mental illness rather than a crime. The first efforts at “gay liberation” were a phenomenon of the early twentieth century. Hot-button issues in the twenty-first include marriage rights for gays and the harsh persecution of homosexuals in more than seventy countries.

Gay men and lesbian women have existed throughout history, although attitudes toward them have varied in different eras. In ancient Greece people tolerated homosexual liaisons under certain circumstances, whereas certain verses of the Hebrew, Christian, and Islamic scriptures speak of homosexual behavior as a grave sin. Negative attitudes toward homosexuality often evolved from interpretations of these scriptures and were written into the civil law in numerous countries. In 2010 more than seventy countries have laws that criminalize homosexuality, and in some countries homosexuality is a crime punishable by death. In 2002, according to Amnesty International, Saudi Arabia executed four men for homosexuality; in June 2009 a homosexual man was decapitated and then publicly crucified in Riyadh after being charged with murder and abduction. In Brazil, according to the international AIDS charity AVERT, 2,509 gay men were executed between 1997 and 2007.

During the Enlightenment the punitive attitude toward homosexuals was replaced in many European countries by the belief that being gay is a mental disease. (The Enlightenment was a philosophic

movement of the eighteenth century marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism.) Instead of being executed, homosexuals were committed to insane asylums. But in England the Labouchere Amendment (named after the British Member of Parliament Henry Labouchere) was passed in 1885, making homosexual conduct punishable by two years in prison. This law would be used to convict the Irish author Oscar Wilde in 1895. It was also exported to all of the British colonies, many of which still had a version of it on the books well into the 1980s. (It was repealed in England in 1967.)

For centuries people seemed to have a “don’t ask, don’t tell” attitude about sexual orientation. Famous people were believed to be homosexual, but modern historians often have a difficult time finding proof because in the past people considered writing in any detail about private sexual conduct to be vulgar. The so-called Boston marriage of Victorian times is a good example: Strong and independent women established loving friendships and lived together as companions, but few documents conclusively show whether these relationships included sex or were mainly platonic.

What we know as “gay liberation” is a comparatively modern phenomenon. In countries such as Germany people made sporadic efforts to change the laws or change society’s attitudes. In Berlin the little-known author Karl Maria Benkert (who later changed his name to “Karl Kertbeny”) became an advocate for the rights of homosexuals (in fact, he is credited with inventing the term); in 1869 he wrote several essays challenging the myths that homosexuals are effeminate or defective and stating his belief that homosexuality is natural (a person is born that way) rather than

In the United States same-sex marriage has become the next frontier for the gay and lesbian rights movements.

Photo by Emily Roesly.

a moral failing. Although he was a man ahead of his time, Benkert's assertions did not become the prevailing views of his era. Occasionally an enlightened doctor or educator would take up Benkert's views. In Germany in 1897 Magnus Hirschfeld, a neurologist, founded the Scientific Humanitarian Committee. Hirschfeld regarded homosexuals as a "third sex" and advocated unsuccessfully for the repeal of laws that criminalized their behavior. When the German Nazi leader Adolf Hitler took power in 1933, groups who taught tolerance of gays were banned, and thousands of homosexuals were later put to death by the Nazis.

In England in 1914 the psychologist Havelock Ellis co-founded the British Society for the Study of Sex Psychology. In addition to educating the public about human sexuality, Ellis taught tolerance of homosexuals; he believed that being homosexual (educators and doctors used the term *sexual inversion*) is not a disease and should not be considered a crime, but his ideas found little support in England at that time. In 1928, when the British novelist Radclyffe Hall published *The Well of Loneliness*, a book that was sympathetic toward its lesbian characters, the British government immediately judged it to be obscene, and all copies were seized.

Early U.S. Gay Rights Organizations

In the United States the Chicago Society for Human Rights was perhaps the first U.S. gay rights organization. Postal clerk Henry Gerber founded it in 1924,

but by 1925 Chicago police had shut it down. Gerber was briefly arrested, he lost his job, and his efforts at advocating for homosexuals received little public support.

In 1951 Los Angeles music teacher Harry Hay and several of his colleagues founded another U.S. homophile organization, the Mattachine Society. It was followed in 1955 by the Daughters of Bilitis, founded by Phyllis Lyon and Del Martin as an advocacy group especially for lesbians. These organizations provided support and encouragement but often did so quietly. Although they sought more respect and tolerance, they also advised members to assimilate as much as possible and to avoid dressing or behaving in ways that would call attention to their lifestyle. Later some militant members of the emerging gay liberation movement would regard the Mattachine Society and the Daughters of Bilitis as accommodationist, too willing to remain in the closet and too afraid to stand up for greater acceptance; but in a society dominated by the conservative politics of U.S. Senator Joseph McCarthy, when homosexuals were often arrested for "lewd conduct," the 1950s were not a good time to be vocal about one's sexual orientation.

Although no single event created the U.S. gay rights movement, most historians agree that the Stonewall Riots were a defining moment. In June 1969 in New York City police raided a gay bar called the Stonewall Inn; such raids were common and usually resulted in numerous arrests. But this time the bar's patrons decided to fight back, leading to three days of civil

Never be bullied into silence. Never allow yourself to be made a victim. Accept no one's definition of your life; but define yourself. • **Harvey Fierstein (b. 1952)**

unrest. In the United States this was the era of the civil rights and women's rights movements, and that environment may have encouraged homosexuals to actively oppose the prejudice they often encountered. The Stonewall Riots mobilized the homosexual community and led to an increasing unwillingness to assimilate or accommodate.

What happened at Stonewall would happen in other cities. In Canada Toronto's gay community was subjected to a series of raids of bath houses in February 1981. Police used sledgehammers and crowbars and arrested 338 people. Members of the gay community were horrified by what they felt was overkill, and the next night four thousand gay men and lesbian women staged a protest march, the largest demonstration of its kind in Toronto. Like Stonewall, the demonstration energized the gay community, making members even more determined to fight for better treatment.

In India, a country where gay and lesbian acts are still criminal offenses, a defining event occurred in December 1998. A movie by the director Deepa Mehta premiered, but this one was unique. *Fire* featured a subplot in which two women fall in love. Religious conservatives were outraged and attacked the theater in Mumbai (Bombay) where the movie was being shown, breaking windows, beating up patrons, and vandalizing the building. Similar events occurred in other Indian cities. However, this time a coalition of civil libertarians, human rights activists, and free speech advocates joined with members of the lesbian community to march and protest both the attacks and the government's efforts to censor the movie. This protest march marked one of the first times that lesbians had been visible in India; most lived hidden lives, afraid to call attention to themselves. The protest march led to the founding of the Campaign for Lesbian Rights. In June 2003 a rally and march were held in Calcutta to protest laws that make homosexuality punishable by ten years in prison; several hundred people marched peacefully in one of the few public demonstrations held by India's gay community.

A number of groups emerged in the United States during the 1970s and 1980s to fight for the rights of gay men and lesbian women. One of the best known was the National Gay Task Force (NGTF) in 1973;

in 1985, it changed its name to the more inclusive National Gay and Lesbian Task Force (NGLTF). The organization not only advocates for changes in discriminatory laws in the United States, but also conducts sociological studies about society's changing attitudes, works with the government to develop strategies to combat violence against gays, monitors the media for antigay content, and conducts international conferences about gay issues. When AIDS first appeared in the United States during the 1980s, NGLTF was at the forefront in combating myths and prejudices and educating the public about HIV. A more vocal and sometimes controversial organization is ACT-UP (AIDS Coalition to Unleash Power). Founded in 1987, it is known for its slogan "Silence=Death" and its commitment to speak out against discrimination in a demonstrative manner, using tactics of civil disobedience called "direct actions." ACT-UP works to change both policy and attitudes about AIDS. Another advocacy group is GLAAD (Gay and Lesbian Alliance Against Discrimination), which was founded in 1985 to monitor the media and advocate for an end to antigay stereotypes in print, broadcasting, and film.

British Activist Groups

In England one of the best-known activist groups is OutRage, founded in 1990. It, too, uses civil disobedience, staging unique and often provocative direct actions to call attention to discrimination and to defend the rights of England's gay community. OutRage is especially good at getting media coverage: Members have staged "kiss-ins," performed a ceremony described as an "exorcism of homophobia," and staged noisy but nonviolent demonstrations at police stations when the group felt that the police were not doing enough to arrest people who attack gays. Another gay rights group in the United Kingdom is Stonewall, which was founded in 1989. It uses lobbying, working with government officials and members of Parliament, to improve the legal rights of gays. Stonewall has also done research on attitudes about homosexuality and sponsored workplace forums so that employers can better understand and support diversity.

Australia seems to have been influenced by the U.S. gay rights movement. Melbourne has a chapter of Daughters of Bilitis. Australia also has a number of activist groups, such as the Tasmanian Gay and Lesbian Rights Group, which has fought for the decriminalization of homosexual behavior. Economic advocacy groups, such as the Australian Gay and Lesbian Tourism Association (AGLTA), also work to find gay-friendly and gay-tolerant hotels and places for visitors to shop.

Criminality

Even in countries where homosexuality is still regarded as a sin or a crime, advocacy groups exist, but they run the risk of being shut down by the government. For example, in Nepal in June 2004 the Supreme Court imposed a ban on the Blue Diamond Society, which advocates on behalf of gay men and lesbian women and conducts HIV/AIDS education. Advocacy groups exist in a handful of Muslim countries (most notably Turkey), but in more theocratic cultures gay men and lesbian women have turned to the Internet to discuss issues while avoiding government crackdowns. In the United States some Muslim immigrants started Al Fatiha (the Opening) in 1997; when it held a conference in 1998, participants came from all over the United States and from South Africa, Canada, Belgium, and the Netherlands to discuss the problems facing gay Muslims worldwide.

Although advocacy has been helpful in many parts of the world, Amnesty International stated in its 2000 report that more than eighty countries still have laws that define homosexual behavior as criminal; twenty-six of these countries are Muslim. (The 64-page 2009 report on state-sponsored homophobia issued by the International Lesbian and Gay Association also lists eighty countries.) In some countries such laws are rarely enforced, whereas in others homosexuals are persecuted. In 2003 Human Rights Watch wrote a report critical of how the government of Egypt rounds up, jails, and possibly tortures homosexuals. In Tanzania the government in April 2004 passed legislation that would make homosexual acts punishable

by twenty-five years in jail. In Poland marchers who attempted to stage a peaceful demonstration in favor of gay rights in June 2004 were attacked and beaten by members of a far-right group called the “Młodzież Wszechpolska” (All Polish Youth), part of the nationalistic and militantly antigay Liga Polskich Rodzin (League of Polish Families).

Perhaps the first country to add to its constitution a provision that outlaws discrimination against gays is South Africa, which did so when its new constitution was written in 1994; an advocacy group, the National Coalition for Gay and Lesbian Equality, had much to do with getting the provision approved. Led by professor Edwin Cameron and gay activist Simon Nkoli, the coalition also has litigated to have laws that criminalize homosexual acts overturned and gained medical benefits for same-sex couples.

Same-sex marriage and civil unions have become a hot-button issue for gay men and lesbian women, and activist groups fight to expand benefits and rights to gay couples. Some people, mostly religious conservatives, have resisted the idea of gay marriage. In the United States, Massachusetts became the first state to permit gay marriages in May 2004; Vermont recognized civil unions in July 2000. Same-sex marriage became legal in Connecticut in 2008, and in Iowa and New Hampshire in 2009. But in a conservative backlash, thirty states have passed laws banning such partnerships. And in California, which briefly allowed same-sex marriages in early to mid 2008, voters reversed the ruling late that year. Worldwide the Netherlands, Belgium, and three provinces of Canada permit same-sex marriage, and a few European countries—France, Norway, Denmark, and Germany—offer limited forms of civil union. Some countries that once criminalized homosexuality are gradually relaxing such laws; in India in 2009, the Delhi High Court ruled that banning sexual relations between consenting gay adults is unconstitutional. But more typical is what occurred in June 2004 in France, when two gay people were married by the mayor of Begles, a suburb of Bordeaux. The mayor, Noel Mamere, was promptly suspended for a month, and the marriage was nullified by the French courts.

And in Uganda, where a constitutional amendment banning gay marriage passed in 2005, the government has repeatedly been accused by human rights groups of harassing gay men and lesbians.

Worldwide many people now see gay rights as a human rights issue, and certainly more acceptance exists than did when the Stonewall Riots occurred. However, as long as conservative religious views predominate, and as long as stereotypes persist, members of the gay and lesbian rights movement will continue their work.

General Agreement on Tariffs and Trade (GATT)

GATT, the General Agreement on Tariffs and Trade, began as a post-World War II document to negotiate policies on international trade. After forty-seven years it culminated in 22,500 pages of text, and an ambitious set of trade-liberalization agreements covering goods, services, and intellectual property. GATT established and was replaced by the World Trade Organization in 1994.

The General Agreement on Tariffs and Trade (GATT) was a relatively informal document created after the World War II to coordinate policies on international trade. Its major aims were the abolition of quotas, reduction of tariff barriers, and promotion of nondiscriminatory free trade. Its origins trace back to 1947 when twenty-three states met in Geneva and negotiated a statement of principles for international trade. This agreement originally was intended to be part of a draft charter for an International Trade Organization (ITO), the third leg of the Bretton Woods economic order, along with the International Monetary Fund and World Bank. The “Havana Charter” of the ITO contained the GATT, as well as provisions relating to employment, commodity agreements, restrictive business practices, international investment, and services. The 1947 GATT, which consisted of negotiated trade concessions and rules of conduct, entered into force as the GATT Protocol of Provisional Application on 1 January 1948, although the rest of the Havana Charter never was ratified, primarily because of opposition in the U.S. Congress. For forty-seven years, the ever-expanding group of contracting parties to the GATT (128 states in 1994) treated the instrument as if it

were a permanent commitment, though actually it was merely a provisional legal agreement. A small secretariat and administrative staff for the GATT was created in 1955 in Geneva, though not as a formal international organization. These personnel were tasked with implementing trade objectives of participating states, namely to apply a nondiscriminatory, most favored nation approach toward trade relations, with tariff reductions presumably based on the principle of reciprocity.

From its creation until 1994, the GATT states engaged in eight negotiating sessions, called “rounds,” to reduce tariffs and produce in piecemeal fashion rules to govern international trade. Nontariff barriers were dealt with after 1965, among them antidumping measures, subsidies, countervailing duties, import licensing procedures, and selective government procurement. These agreements were contracted by only a few of the GATT members, mainly those who were members of the Organization for Economic Cooperation and Development (OECD).

The final GATT negotiating session, the Uruguay Round, proved the most prolonged and most comprehensive. It lasted from 1987 through 1994 and established a legal institution—the World Trade Organization—to replace the GATT of 1947 with all its amendments. Established by the Marrakesh Protocol on 1 January 1995, the WTO is a multilateral institution charged with administering rules of trade among member countries. Legally it embodies an international intergovernmental organization, possessing international personality (that is, the WTO possesses international legal rights and duties, with the capacity to bring or defend legal claims between states) and competence in its own right independent

of its member governments. Consequently, the WTO enjoys legal privileges and immunities necessary for the exercise of its mandate. As a body of legal rules, the WTO contains the GATT of 1994 and other non-goods-related agreements.

The WTO represents the preeminent international body dealing with the rules of trade between states. The 153 members of the WTO in 2009 account for more than 97 percent of world trade, and its decisions affect nearly all the goods and services moving in international commerce. At its core are the WTO agreements, which operate as the ground rules for international commerce and trade policy. The main objectives of the WTO agreements are to assist trade to flow freely, achieve liberalization through negotiation, act as a forum for trade negotiations, and ensure impartial settlement of disputes. Succinctly put, the WTO's aim is to facilitate the free, fair flow of trade in a predictable fashion for its member states.

The WTO provides both a code of rules and a forum for governments to discuss and resolve trade disputes and to continue negotiations toward expanding world trade opportunities. The WTO includes all the GATT provisions for trade in goods, plus rules developed for trade in services and intellectual property, as well as rules and procedures governing the settlement of disputes. It operates as the principal international body concerned with multilateral negotiations on the reduction of trade barriers and other measures that distort competition. In this regard, drawing heavily from the GATT legacy, the WTO embraces five fundamental principles that establish the foundation of the modern multilateral commercial system: (1) nondiscrimination through most-favored-nation treatment (MFN); (2) freer fair trade; (3) more predictable trade policies; (4) encouraging open and fair competition; and (5) concessionary treatment for less developed countries.

The WTO's rules, called agreements, were negotiated during the GATT's Uruguay Round. These rules run some thirty thousand pages in sixty agreements and separate commitments (called schedules), and set out acceptable procedures for customs duties and opening markets. Through these agreements WTO members operate in a nondiscriminatory trading system that upholds their rights and obligations. Each state is guaranteed that its exports will be treated fairly and consistently by other members of the WTO. The Uruguay Round produced 22,500 pages of text that list individual countries' commitments to cut and bind customs duty rates on imports of goods, which entailed the most ambitious set of trade-liberalization agreements in the GATT's history. The WTO agreements cover goods, services, and intellectual property. They articulate principles of liberalization and permissible exceptions. They prescribe special treatment for developing countries. They require governments to make their trade policies transparent. With the formal conclusion of the Uruguay Round on 15 April 1994, the GATT went out of existence.

Genetics

Genetics concerns the scientific study of inheritance and variations in living organisms. While it has long been known that “ancestors” passed on certain traits to their “offspring,” from around the mid-nineteenth century it became evident that organisms inherit these traits via distinct units, now known as genes. Genetic change occurs over time through mutations and natural selection or evolution.

The most recent common ancestor (MRCA) to humans and to the nearest primates, chimpanzees, lived in Africa, most probably in the tropical forest, 5 million years ago, a date that some prefer to set somewhat earlier, by 1 or 2 million years. The forest is still the environment where chimpanzees and earlier ancestors like gorillas and orangutans lead arboreal lives. Because bone conservation is not good in a forest environment, almost every known intermediate ancestor in the direct line to humans comes from drier environments in the Rift Valley, extending from East Africa to South Africa. This is where almost all the earliest human fossils were found.

Two major evolutionary changes were observed in the human line but not in the simian lines: the transition to the erect, bipedal posture, which favored greater speed on the ground and also freed the hands for the making and use of tools, and an apparently continuous increase in brain size. The latter, and the development of phonation organs, may have facilitated the genesis of articulated speech, which is not present in primates, although they can be taught the meaning of hundreds of words, using special teaching techniques. The capacity to form complete sentences makes the transmission of complex thoughts possible.

The capacity to communicate using language that is typical in the human species is a real source of human superiority to all other vertebrates, probably the most important one. It must have been the major skill that made it possible for a relatively small group of East Africans to grow and expand across the whole Earth, starting about a hundred thousand years ago. The information about this comes from paleoanthropological and archeological observations that offer dates and places. The evolution from the MRCA to modern humans was, however, long and slow, with several culs-de-sac, but a common evolutionary theme throughout the human line is an increase in brain size, by a factor of four times, as judged from the size of the brain case.

One particularly well-dated woman, *Australopithecus afarensis* (Lucy), 3.2 million years old, may be at the origin of the bifurcation into an extinct line leading to several Australopithecine species, and that leading to *Homo sapiens sapiens* (the species to which we all belong). The genus *Homo* is given an age of about 2.5 million years and is characterized by the first use of rough stone tools, hence the first species of the human genus is called *Homo habilis*. Some improvement in shape and increased variation of shapes and uses of tools is noticeable at the time of *Homo erectus* (dated about 2 million years ago). There is currently a tendency to rename these fossils, but we retain the simpler, earlier terms. *H. erectus* is the human who, starting 1.7 million years ago from Africa (where the Rift Valley is still the only source of finds) relatively quickly settled most of Europe and Asia.

The slow increase in brain size stopped around 300 kya (300,000 years ago). For a long period, between 500 kya and 40–30 kya, two types of humans

Francis Crick, who with James Watson obtained new insights into the complex structure of the DNA molecule, made this pencil sketch of the double helix, the twisted ladder of genetic code.

in different parts of the world were particularly successful and left a greater number of fossil proofs of their existence. One type, Neanderthal, lived in Europe and extended to western Asia, reaching the Middle East between 80 and 60 kya. According to some anthropologists, Neanderthal was the ancestor of modern Europeans, but recent genetic work on fossil remains has shown that it became almost certainly completely extinct. According to others, the branch leading to all modern humans developed in

Africa, in the Rift Valley. The only fossil predecessors of modern humans were found in Africa. Two recent finds, an *erectus* of 1 mya found in Eritrea, and a 150 ky-old almost perfectly modern skull found not very far away in Ethiopia, filled important gaps and have helped to show a continuous evolution in East Africa of modern humans from the earliest types.

Genetic Analysis and Human Migration

Genetic analysis of human evolution was started very soon after the discovery of genetic variation. At the beginning the only frequent (polymorphic) genetically variable traits inherited in a clear-cut way according to Mendel's laws were blood groups ABO, RH, and others. These traits are inherited equally by both parents and could be used to prove the influence of the four standard factors of evolution and to follow their effects quantitatively thanks to the mathematical theory of evolution, developed in the 1920s and 1930s by Ronald Aylmer Fisher, John Burdon Sanderson Haldane, and Sewall Wright.

The first factor, *mutation*, is the source of all inherited differences, which we now know are changes in DNA: a linear molecule formed by a chain of four simple substances called nucleotides or bases—A, C, G, T—attached one to the other, that are reproduced and passed to descendants in the same order in which they were in the parents. Human DNA is made of 3.1 billion bases divided in twenty-three filaments of unequal length, the chromosomes. Mutation is a transmissible change in DNA: the smallest and most frequent one is the replacement of one of the nucleotides by another of the four. It happens spontaneously at a very low rate. A mutant (an individual carrying a new mutation) may increase in relative frequency over the generations because of *natural selection*, when it has an advantage over the parental type, either because it survives some disease or other unfavorable environmental condition better and/or is more fertile. When mutation is more disadvantageous or even deleterious than advantageous, carriers tend to be eliminated by natural selection and then

Researchers in the genetics laboratory at Iowa State College. Ames, Iowa, May 1942. Photo by Jack Delano, Library of Congress.

the mutation disappears. Most mutations, however, are neither advantageous nor disadvantageous (i.e., are selectively “neutral”), and their permanence in the population, their decrease, increase, or even fixation at the end, are determined exclusively by chance. Like natural selection, this phenomenon, called *random genetic drift*, causes changes in the frequencies with which all the types of genes caused by mutation are found in populations in successive generations. Both selection and drift tend to differentiate a population from all others. Natural selection causes adaptation to the environmental conditions in which an organism is living that change with time or place, while drift acts only according to the laws of probability. Drift therefore causes changes of greater relative magnitude in populations that are of smaller size.

Migration of individuals from one population to another tends instead to homogenize populations whose genetic differences have been caused by selection or drift or both. But when a group migrates to a previously unsettled area, it may expand demographically and create a new population that, if successfully settled, will eventually grow and differentiate from the original one. Under these conditions migration of a group to a new area may cause differentiation, and it enhances drift effects, especially if the migrating group is small.

Genetic considerations lead us to conclude that modern humans derive from one small population of perhaps one or a few thousand individuals in East Africa that started expanding slowly across Africa about 100 kya. Members of this small group, a tribe, must have almost by definition spoken a single language, which was probably as sophisticated as any language existing today. Like practically all humans until then, they were hunter-gatherers (also called foragers), living in small groups at very low density (on the order of 0.1 inhabitants per square kilometer), and roving semi-nomadically within their hunting territories.

Around 50 kya, a group in a very similar area started expanding more rapidly, demographically and geographically. They were probably helped by some innovations, like rough navigation means, and a new more-sophisticated stone tool set, in addition to modern language, which they most probably shared with those ancestors who were responsible for the first slower expansion of 100 kya. They may have traveled along the southern coast of Asia, using rough navigation means; evidence for this comes mostly from the fact that from Southeast Asia they reached New Guinea and Australia and had to cross various long tracts of sea. They also reached Central Asia from which they moved out in all directions: east to East Asia, north to Siberia and America via the Bering

Most intellectuals today have a phobia of any explanation of the mind that invokes genetics. • **Steven Pinker (b. 1954)**

Strait (probably all emerged at the time of the crossing, before 10 kya), and west to Europe. The expansion from Central Asia was especially rapid. After more than 10 kya, all the land inhabited today, except Polynesia, had been settled (it was settled between 6 and 1 kya, using sophisticated boats and navigation systems, starting from Taiwan or the Philippines).

After 13 to 12 kya, the last glaciation ended and there were changes in the flora and fauna as a result of the weather change. In many parts of the world, especially in temperate areas like the Middle East and the Nile Valley, in China and on the Mexican highlands, people started living on cereals (wheat and barley in the first region, rice in southern China and millet in the north, and in Mexico corn and many other vegetables). In areas in which cereals became the major food source, it became convenient to practice agriculture, which brought crops closer to home and made it useful to build more permanent houses. Nomadic habits were largely replaced by domestic ones. In some regions wild animals were easily domesticated. In the Middle East it was possible to domesticate sheep and goats, pigs, cattle, and later horses (north of the Black Sea and the Caucasus). In northern Syria, a mixed agro-pastoral economy was already developed by 11,500 years BP (before the present). It is possible that Europe owes its presently flourishing economy to having been able to develop the most effective domestic animals.

The story of the recent peopling of the world was first modeled by reconstructing trees of populations tested for standard genetic markers and using genetic distances between population pairs calculated from the frequencies of genetic traits in pair members. One way to reconstruct a tree is to start from the nearest populations (having the smallest genetic distance) and continue bringing all the population pairs together in order of increasing distance until the root of the tree is reached. The best way to reconstruct the root involves using remote ancestors for traits comparable to those used in the analysis of the group of populations. It became clear that trees reconstructed were the same irrespective of the genetic traits used, provided adequate numbers of traits are employed.

The independence of conclusions, irrespective of the type of genetic traits studied, is an important guarantee that we can trust them.

Since the 1990s or so it has become possible to reconstruct trees of markers that are found only in males (Y chromosomes) or are found in both sexes but are transmitted only by females (mitochondrial DNA or mtDNA). These can be studied in single individuals rather than in populations, and the trees reconstructed in this way are true genealogies. For technical reasons they are particularly accurate and free from doubt for the Y chromosome, but there also is significant agreement between genealogies of mtDNA and Y chromosomes, apart from well-understood exceptional behavior in specific populations that have specific marriage customs. These studies have confirmed results obtained on gene frequencies of populations for markers carried in the usual chromosomes and have contributed sharper conclusions on dates and places of major events in human prehistory.

The Importance of Agriculture

The introduction of agriculture was probably a reaction to need: the hunting-gathering economy practiced until then was not sufficient to guarantee enough food, making food production necessary. It inevitably started a continuous raise of population density, in spite of fluctuations due to accidental severe disturbances. In the 90,000 years prior to the beginnings of agriculture, the population had increased from the initial one or few thousand at the start of growth, by a factor of at least 1,000. In the last 10,000 years, agriculture raised population numbers by another factor of 1,000.

The spread of farming around the places of origin is an unavoidable effect of the increase in the number of farmers made possible by the increase of available food that farming generated. When local population growth rapidly reached saturation, it caused migration to nearby areas in search of new fields. This search also was promoted by the rapid exhaustion of the soil caused by primitive agricultural methods. There were continuous technological improvements

like plowing and irrigation over long periods of time, which also created new problems, for example, desertification due to soil salinization in the Middle East or overgrazing in the Sahel. Nevertheless, farming expanded from the place of origin over long periods at a constant rate, estimated at 1 kilometer per year toward Europe (where a better archeological coverage permits an accurate average estimate of the rate of spread). The expansion was determined both by the higher growth rate of the number of farmers (called demic diffusion) and by technological adaptation by local hunter-gatherers (cultural diffusion of the technology).

Genetic studies show different results for the relative role of the genetic/cultural contribution of original farmers to the genetic constitution of European men and women. The problem gave rise to an intense scientific debate, still not completely settled, but the results indicate from 50 to 60 percent demic diffusion for males, and 20 percent for females, or an average for the two sexes that is around one-third genetic and two-thirds cultural. Another example of demic diffusion due to agriculture is found in the Bantu expansion from Cameroon to South Africa, which started about 3,000 years ago and only recently came to an end. Here also, there is a less well investigated but clear male-female difference in the same direction. Hunter-gatherers are everywhere considered socially inferior, and passage to the social class of “farmer” ordinarily was permitted only to females through marriage to a member of the higher class (hypergamy). Male polygamy (polygyny), probably more frequent among farmers, also helped in the same direction.

Farming was initiated everywhere while tools were still made of stone. In Europe (but not in Japan), the term *neolithic* (as opposed to *paleolithic* or *foraging*) refers to the presence of agriculture, which caused a change. The European neolithic adopted ceramic around 3,000 years after the inception of farming, while in Japan ceramics developed much earlier (almost 12 kya), but agriculture entered from Korea only about 2,000 years ago. Technological developments have driven genetic, cultural, and social evolution of modern humans from the very beginning.

The next major innovations after farming were the introduction of metals, first bronze, beginning some 5 kya, probably in eastern Europe, followed by iron 3,500 years ago. The spread of these two major technical developments to the rest of the world was much more rapid than that of agriculture. Metal technology contributed greatly to the development of war. Its beginnings tend to be similar in several areas to that of writing (and therefore of recorded history).

Benefits of Genetic Variation

The recent origin of all modern humans from a single, small population living in a narrow area explains why human living populations show small difference: There was not enough time for the generation of much genetic differentiation among the populations that dispersed over the Earth. We can, however, guess the geographic origin of individuals on the basis of some external traits like skin color and facial and body traits that represent the adaptation to a highly varied set of environments, and that differ by climate, flora, and fauna. But each population, even if small, harbors considerable genetic variation, which ensures its survival in the face of new and unpredictable challenges.

In general, high genetic variation is beneficial to a population. Pure races are a fiction, and even if they were possible, they would be truly undesirable. By contrast, cultural differentiation, for instance, the linguistic one, tends to be greater between than within populations. Culture—intended as the knowledge, customs, habits, and values accumulated over generations—needs to be sufficiently homogenous for the harmonious life of a society, in the same way that language spoken by individuals living together must be similar enough for it to achieve its major purpose, mutual understanding.

Genocide

Genocide is the deliberate and systematic attempt to destroy, in whole or in part, a national, ethnic, racial, or religious group. The equivalent of what we now call genocide has occurred throughout much of human history, but the term was not coined until Raphael Lemkin applied it to the Nazi occupation of Poland and subsequently to the Holocaust.

The word *genocide* is a modern term for an ancient practice. It was first coined by a Polish jurist, Raphael Lemkin, who sought to describe the Nazi occupation of Poland as one designed to eliminate Polish identity. Lemkin's initial work is sometimes erroneously linked to the Holocaust. Nevertheless, it was the Holocaust and its aftermath in the post-war United Nations that led to the formulation of the 1948 United Nations Convention on the Prevention and Punishment of the Crime of Genocide, which remains the principal accepted definition of the practice. Article II of the convention (Chalk and Joassohn 1990, 44–49) defines genocide as follows:

In the present Convention, genocide means any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such:

- (a) Killing members of the group;
- (b) Causing serious bodily or mental harm to members of the group;
- (c) Deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part;
- (d) Imposing measures intended to prevent births within the group;
- (e) Forcibly transferring the children of the group to another group.

While this formulation is not without some controversy, it is plain that massacre, a practice most commonly associated with genocide, is only one aspect of its perpetration. This is because genocide is essentially a crime of identity: Its objective is to eliminate some form of cultural identifier rather than, necessarily, to slaughter those who identify with it. Historically, however, the most direct means of achieving a genocidal objective has been mass murder, although other, more indirect means have also had currency throughout history. Moreover, one controversial aspect of the convention is its omission of political groups. This reflects its origin as a document negotiated in the senior echelons of the United Nations, and has led some scholars to seek to supplement the term genocide with further terms, including “politicide” (Harff and Gurr 1988, 359–371) and “demicide” (Rummel 1994).

It is worth noting that the disappearance of any culture, or cultural group, is not in itself necessarily evidence of genocide. In world-historical terms, cultures have their own lives. The processes of decay, decline, and assimilation are often unforced, driven by voluntary cultural shifts in response to the realities of social and linguistic hegemonies. Over centuries, for example, the dominant Zoroastrian faith of Iran has given way to Shia Islam; languages like Oscan, Lycian, Coptic, Sogdian, and Breton gave way to Latin, Greek, Arabic, Pathan, and French.

As a comprehensive phenomenon, genocide is more modern than it is ancient. Cultures like the Assyrians and Hebrews talked genocide in the ancient world, but lacked the technology to achieve it. The Book of Joshua makes claims about the utter destruction of the peoples of pre-Hebrew Palestine which cannot

be borne out archaeologically. In the same way, the Annals of the Assyrian kings make extravagant claims about the utter annihilation of peoples who were not, actually, annihilated. The ancient Greeks, with the more limited objective of the elimination of rival city-states, were more successful, inventing the practice of *andrapodismos*: the slaughter of the adult males of a city and enslavement of the remainder. This was visited by the Crotonians against the Sybarites; the Athenians upon the Melians and Scionians; the Thebans upon the Plataeans; and Alexander's Macedonians upon the Thebans. The Romans inherited this practice, killing and enslaving all of the Carthaginians and sowing their fields with salt (Leadbetter 1999, 272–274).

These massacres remain the exception rather than the rule in antiquity. There were social identifiers for ancient people, as for modern, which invited genocidal intent. What prevented a wider and more savage manifestation of genocide was the lack of requisite technology to carry out such acts. The principal identifiers that have emerged over time are religion; imperial identity; nationalism; political identity; and ethnicity, sometimes nuanced as race.

Genocide and Religion

Religious conflict has been common in world history. From time to time, these conflicts have been genocidal, particularly with the emergent dominance of exclusivist monotheistic religions in the Middle East and Mediterranean from the fourth century CE onwards. Traditional polytheistic religion was, nevertheless, not immune from the genocidal impulse, principally because it was embedded in the ideological structures of the state. In the third century, for example, the Roman state made a systematic attempt to eliminate the Christians and Manichaeans, who threatened the religious foundations of imperial ideology. Likewise, in the eleventh century the Hindu king of Pandya in India sought to eliminate the Jains, impaling over eight thousand of them.

While such instances of genocidal practice are linked to traditional pagan and polytheistic religions, a significant impetus for genocidal violence also came with the emergence of Christianity as a hegemonic religion in Europe. This violence initially focused on the emergent Islamic communities of the Middle East. The crusading movement, in particular, was principally directed at the Muslim communities of the Levant. While this aspect of the crusading movement failed to eliminate Islam in Palestine, other crusades had more murderous success. The most notable of these was the crusade against the Albigensians, or Cathars, a Manichaean community centered in the Languedoc region of southern France. This crusade took the form of a series of military campaigns conducted between 1208 and 1226, which were marked by atrocity and indiscriminate massacre, notably the massacre of the entire population of Béziers in 1209. Even after the conclusion of military hostilities, the Inquisition continued the work of eliminating Albigensianism.

The Inquisition, founded largely as a consequence of the emergence of Catharism, was the principal genocidal agency in Europe until the Reformation. It hunted Hussites, witches, Waldensians, and, from time to time, Jews. The Reformation entrenched religious diversity in Europe, but genocidal massacres still occurred from time to time, most notably the St. Bartholomew's Day massacre of French Protestants (Huguenots) in 1572. Christians could be victims too. The Jesuit missionaries based in Japan were expelled in the early seventeenth century and Japanese Christian converts were tortured and killed, with the result that Christianity was eliminated from Japan until the Meiji period.

More recently, the emergence of an intolerant version of political Islam has seen eliminationist assaults on the Baha'i community of Iran. Almost inevitably, genocide on religious lines is associated with the use of religious language by political authorities. This reflects the fact that genocide is a crime almost exclusively committed by those who have political power to use violent means over those who do not.

Throughout history, it has been the inaction of those who could have acted; the indifference of those who should have known better; the silence of the voice of justice when it mattered most; that has made it possible for evil to triumph. • Haile Selassie (1892–1975)

Genocide and the Imperial State

Genocidal practice has been inherent to imperial powers from the earliest times. While most empires have been consciously multicultural, they are all established and maintained by violence, a class of which is designed to eliminate particularly recalcitrant opponents in order both to prevent further resistance and also to terrorize the remainder into acquiescence. The Persians destroyed Miletus during the Ionian Revolts; Alexander obliterated the city of Plataea; the Romans targeted and sought to eliminate the Druids; in the fourteenth century Timur (Tamerlane) established an empire across Eurasia based upon the terror inspired by genocide. In his campaigns in India, he slew all of the inhabitants of Batnir and Meerut, marking his progress with vast pyramids of heads. He marked his 1399 capture of Delhi with four of these, at each corner of the city. He punished the rebellion of Isfahan in 1387 by massacre, and a tower of seventy thousand skulls was piled up. Genocidal massacres were also employed in his capture, variously, of Baghdad, Damascus, and Tiflis (Katz 1994, 94).

The impact of the imperial encounter between the Old World and the New was immediately genocidal.

Some methods used by European colonizers to drive Native Americans from their land fit the modern definition of genocide. This drawing shows dogs set upon Native Americans in Maine in the 1600s.

In 1519, Hernán Cortés slaughtered or deported all of the inhabitants of the town of Cholula, and in 1521, he marked his recapture of the Aztec capital of Tenochtitlán by the massacre of its surviving inhabitants, in the course of which an estimated 100,000 people were slain (Churchill 1997, 98). The muskets and cannon of the conquistadors were accompanied by the smallpox pathogen. While there is some (relatively late) evidence of the deliberate infection of indigenous people with smallpox in North America, such an act was largely unnecessary. Smallpox, typhus, and other imported diseases wrought havoc among the indigenous peoples, leading within a few decades to unsustainable population levels (Stannard 1992, 102–112; Churchill 1997, 129–157). In respect to the European discovery of the New World, particularly the confrontation with its indigenous peoples, it has been argued that “the sixteenth century perpetrated the greatest genocide in human history” (Todorov 1984, 5).

Colonial Empires

The establishment of the New World empires of Spain, Portugal, France, and Great Britain marked a major expansion—indeed a globalization—of European power. They are also a clear instance of small émigré elites subjugating a vast indigenous population. This was a process facilitated by disease, but also marked by an especially ruthless brutality toward indigenous peoples which can only be described as genocidal. There was resistance, but the strength of native arms was sapped

by disease and thwarted by technology. Arrows and spears might match muskets, cannon, and rifles in occasional skirmishes, but they could not win the long wars of attrition waged in North and South America, and in Australia, by colonial occupiers. Many of these policies have persisted until relatively recently. In Australia and elsewhere, the genocidal practices which marked the frontier conflict between indigenous people and British colonists resulted in massacres and campaigns of extermination. These were succeeded, during the course of the twentieth century, by a more subtle policy of marginalization and the forced removal of children to “breed out the color.” This policy even persisted after 1967, when indigenous Australians were granted full citizenship rights, and was the subject of a major investigation in Australia in the 1990s (Tatz 2003, 67–106).

In a similar way, the economic development of the Paraguayan countryside was accompanied, in the 1950s and 1960s, by the slaughter of indigenous Aché (or Guayaki) people. The Paraguayan government, charged with genocide in 1974, pleaded in its defense to the U.N. Human Rights Commission that no genocide had been committed since there had been no intent to eliminate the Guayaki as such, merely the pursuit of an economic objective, which had been hindered by people who happened to be Guayaki.

Colonial occupations in those instances were genocidal in nature principally because the occupying colonizers were also settlers. In other places, colonial empires took a different form, with minority colonizing elites dominating majority indigenous populations. In such places, the colonists’ principal interest lay in the economic exploitation of the colony and its peoples. In these circumstances, genocide is less likely to occur although, as Jean-Paul Sartre has argued (1968), the imbalance in the power relationship between the colonizer and the colonized is frequently maintained by the practice of genocidal massacre.

There were a number of spectacular examples of this in Africa during the colonial period. In the Belgian Congo, the quota system for the harvest of wild

rubber imposed upon the inhabitants by the personal administration of Leopold II was genocidal in impact rather than intent. The devastation it wrought upon the peoples of the region led, in 1907, to the Belgian Parliament humiliating their own monarch by the formal annexation of the Congo, thereby replacing Leopold’s authority with their own.

A clearer and more unambiguous case is the response of German authorities to the uprising among the Herero people of Namibia in 1904. Initially successful because of the group’s numerical superiority, the Herero rebellion soon faced a counterattack under the command of General Lothar von Trotha. The general so disposed his forces as to drive the Herero into the waterless Omaheke desert, within which they were contained until they perished of thirst and exposure. In 1903, there were eighty thousand Herero; a few years later, a scant fifteen thousand remained. This was a clear attempt at colonial pacification through genocide, and was followed up by a similar assault on the Nama people, of whom over half were slaughtered between 1907 and 1911.

Just as the process of colonization generated genocidal conflicts, so did decolonization. In many cases, colonial borders were drawn by the colonial powers without regard to the cultural and religious identifications of the subject populations. As these colonial boundaries have persisted beyond the colonial period, genocidal civil conflict has frequently been the result. In the Sudan, a bitter genocidal conflict between the Arab Muslim north and the Christian/animist Bantu south persisted for many decades, and was noted for an attempt by the north to subjugate the south by the imposition of permanent famine conditions. A similar state of affairs now prevails between ruling northerners and the peoples of Darfur in western Sudan.

Genocide and the Nation-State

The problem that decolonized regions face, and that has resulted in genocide, is the need for colonial territories to reinvent themselves as nations. The nation is the ideal form of post-Enlightenment state, created

in Europe to redefine polities that had been created by centuries of dynastic competition. The nation-state emerged after the Peace of Westphalia of 1648 and was affirmed by French Revolution, which first embodied and articulated a clear nationalist principle. Nations construct themselves through a matrix of linguistic, religious, and cultural identifiers.

Inherent Genocides

Sometimes those identifiers are inherent. The most obvious of these is heredity, or “race.” It was a particular concept of race used by the Nazis to construct their peculiar vision of Germany. They used it, more specifically, to seek to eliminate all Jews. The Holocaust has a particular standing in the history of genocide since the victims were defined biologically, and so could not thwart the Nazi perpetrators by conversion. It also meant that the perpetrators were compelled, by the logic of their own vision, to slaughter all of their victims. The most sophisticated technology (for its day) was employed: railways to transport the victims; gas chambers to kill them en masse. Alongside that, more rudimentary technologies were also employed: shooting; starvation; exhaustion; disease.

The Nazi vision of a biological utopia led them also to target groups other than Jews. Famously, they sought to slaughter all the Roma and Sinti (“Gypsies”) despite their Aryan origins. They also targeted Jehovah’s Witnesses, homosexuals, and (what Nazis thought of as) similar groups of adherence, although in these cases, it was possible to escape death through a denial of the relevant identity. Alongside these directed policies was also the genocidal policy adopted in Poland which led Raphael Lemkin initially to devise the term. The Nazis were ultimately responsible for the deaths of an estimated 5 to 6 million Jews, including 3 million Polish Jews; as many as 3 million Soviet prisoners of war; up to 2 million Christian and other (non-Jewish) Poles; somewhere between a quarter to 1.5 million Roma and Sinti (Gypsies); 200,000–300,000 people with disabilities; 100,000 Communists; 10,000–20,000 homosexuals; and up to 5,000 Jehovah’s Witnesses.

Nazi policies have rarely been imitated, although it is arguable that the ethnic identifiers used in the genocides in Burundi and, later, Rwanda, are of a similar type. The situations in these states are more or less identical to one another. Both are postcolonial states; both were occupied by the Germans, and then, as mandatory power, by the Belgians, who continued the German policy which privileged one ethnic group, the Tutsi, usually in a minority, at the expense of the other, the Hutu. This has resulted in a post-independence history of mutual massacre. Between 1972 and 1975, at least 100,000 Hutu were killed in Burundi by the (all-Tutsi) army; in 1994, approximately 1 million Tutsis were murdered in Rwanda by Hutu *Interahamwe* militias. The Rwandan genocide at least was a last-ditch attempt by Hutu hardliners to prevent the implementation of a compromise peace (the Arusha accords) reached with the Tutsi-dominated Rwandan Patriotic Front. Along with ethnic Tutsi, the victims included moderate Hutus, the Hutu president who had signed the accords, Juvenal Habyalimana, the prime minister, Agathe Uwilingiyimana, and other supporters of ethnic compromise.

Adherent Genocides

Nation-building can also result in what might be called adherent genocides. This occurs particularly in cases where the nation is aligned with a particular religious or ideological view. A prime example of this is the Terror during the French Revolution, when as many as twenty thousand people were executed because they either were, or identified with, members of the old French aristocracy. In the same way, the late Ottoman state, struggling to redefine itself as ethnically Turkish, and deeply mistrustful of the Christian Armenians straddling the Russian border, slaughtered over 1.5 million Armenians during the latter half of 1915. It was possible for Armenians to escape death, through conversion to Islam, and some accepted this road to survival, thus rendering this a genocide more based on adherent than inherent qualities.

The most notable case of adherent genocide is the Soviet Union under Stalin. Stalin routinely used

genocide as a tool of state control, attacking both social classes (kulaks) and ethnic groups (notably the Ukrainians and Tatars) through a combination of massacre, deportation, and enforced famine. There is no accurate estimate of the total number of Stalin's victims although it can reasonably be assumed that there were in excess of 30 million.

In the late 1970s, a peculiar case of adherent genocide occurred in Cambodia. There, a militant Stalinist regime led by Pol Pot, the Khmer Rouge, sought to reimagine the country as a series of peasant collectives. Any person not meeting the state's definition of a Cambodian peasant was liable to be slain: intellectuals (often perceived simply as people who wore spectacles), the Muslim Cham people, Buddhists, and all non-ethnic Cambodians. Over 1.5 million people were killed before the slaughter was brought to an end by the fall of the Khmer Rouge regime at the hands of the intervening Vietnamese.

Genocide Denial

One ongoing feature of the historiography of genocide is the unwillingness of many perpetrator states, or their successors, to accept the fact that genocide has occurred. The Turkish state, for example, has long denied the fact of the Armenian genocide, despite the mountain of evidence to the contrary. Neo-Nazis and various sympathizers deny the Holocaust, and colonial successor nations are frequently unwilling to acknowledge the more sordid deeds committed by their pioneers. It is both embarrassing at a time when new nations are seeking to construct more heroic foundation narratives, and it is legally problematic since it opens up the possibility of prosecutions, lawsuits, and compensation claims.

Genocide in the Future?

The 1990s were a particularly bloody decade. The breakup of the former federated republic of Yugoslavia resulted in a series of Balkan wars and two converted genocidal assaults, one on the Bosnian Muslims, the other on the Albanians of Kosovo. These, together

with the genocide of the Tutsis in Rwanda in 1994, resulted, first, in the creation of the U.N. War Crimes Tribunal for the Former Yugoslavia and Rwanda and, later, in the 1998 formation of an International Criminal Court for Genocide and Major Human Rights Violations. The latter formally came into operation in 2002; it provides the first international standing court through which both survivors and bystander communities can seek redress from perpetrators. As of 2010 it has 111 member countries, although China, India, Russia, and the United States have not joined.

The conditions that generate genocide still exist in states and parastate organizations (that is, liberation and paramilitary organizations), although a number of early warning systems are in place to try and detect potential genocides before they occur, and there is greater opportunity for judicial redress after the fact. Despite the fact that the Genocide Convention demands external intervention to prevent it, there must first be a willingness to recognize and name genocide wherever it occurs, and this is not always freely forthcoming.

Geographic Constructions of the World

In order to grapple with the complexities of global geography, it is necessary to construct abstract models of the world, ordering space into comprehensible frameworks. All intellectual traditions are marked by such geographic constructions. Through spatial categories, people divide their known worlds into regions that can be named and known in relationship to one another.

Typically, geographical constructions are based on an ethnocentric conception of space, focused on a particular group's homeland. In pre-modern times, most peoples placed their territories at the center of the world. For the ancient Greeks, the ritual center at Delphi formed the navel of the earth, whereas the Chinese literally regarded their country as the Middle Kingdom. Religious ideas and legacies of cultural borrowing, however, sometimes displaced the "center" into foreign lands. Medieval Europeans thus typically regarded Jerusalem as the global heartland, while the Japanese framed their islands as "eastern" due to the centrality accorded to China in the Confucian tradition and to India in Buddhist scriptures.

Ethnocentrism and Cosmology

Ethnocentrism has also molded the scales on which regional divisions have been constructed. Typically, a given society's own lands are subdivided into a fine mesh of distinctive regions, whereas vast expanses of terrain in more distant reaches are lumped together. A text from tenth-century Persia (*Hudud al-'Alam*), for example, divides the world into fifty-one units, nine

of which cover portions of present-day Iran, whereas one suffices for all of Europe north of Spain and west of Russia. In traditional South Asian global visions, China and Arabia were so marginal as to virtually disappear from view.

A second feature of most pre-modern geographic constructions was their cosmological orientation. Patterns of terrestrial order, in other words, were mapped onto those of the cosmos, as interpreted through religious or philosophical doctrines. Hindu and Buddhist conceptions of the world, for example, were ordered around the notion of a central "continent"—Jambudvipa—that was in turn surrounded by a series of concentric, ring-like oceans and landmasses. While Jambudvipa had features that could clearly be identified with real places, the outer continents existed largely as conceptual space. Medieval Europeans' constructions of place were similarly guided by religious ideology. Thus in the so-called T-O maps of the time, which literally showed a "T" figure inscribed within a circle, the Mediterranean Sea and the Nile and Don rivers form a central cross that structures the world, separating the three continents: Europe, Asia, and Africa. This Trinitarian division of the world (held to reflect the patrimony of Noah's three sons, Ham, Japhet, and Shem) was so deeply ingrained that the discovery of a fourth landmass, the Americas, resulted, according to Eviatar Zerubavel (1992), in "cosmological shock."

Constructions of the Classical and Islamic Worlds

Not all premodern systems of world geography were wedded to overtly religious doctrines. The

The *Ch'onha chido* (Atlas of the world) was the traditional Korean atlas produced in the early Choson dynasty (1392–1910).

constructions of classical Greek and Roman geographers, for example, were based more on geometrical and astronomical theorizing. Central to their conceptual schemes was the notion of *clima*, or latitudinal belts, distinguished from each other by differences in day length and sun angle. Different *clima* supposedly produced different kinds of human bodies, with corresponding customs and forms of government. Abstract theorizing often led classical geographers to imagine alter-worlds that were no less fanciful than the ring-like continents of Buddhism. To preserve the symmetry of the globe, for example, it was often thought that a large landmass, roughly equivalent to Europe, Asia, and Africa, had to exist in the southern hemisphere. This notion was not fully put to rest until the eighteenth century.

Traditional Islamic conceptions of the world relied heavily on classical Greek models, giving precedence to latitudinal belts. Muslim geographers, however, also mapped their historically embedded religious concepts across the face of the earth. Their main division contrasted an ideally expanding realm of submission to God (*dar al-Islam*), where peace would

theoretically prevail, with a realm of war (*dar al-harb*), where religious error and strife reigned.

Imposition and Evolution of the European System

In the last hundred years, traditional non-Western geographic constructions have been largely replaced by those of European origin. After the age of exploration, European knowledge of the world surpassed that of any other civilization, and as European power expanded, ideas of Western origin were forced on, or adopted by, peoples of other regions. The traditional Japanese three-country global model, based on the primacy of Japan, China, and India, for example, could no longer be maintained after Dutch atlases began to circulate in the early modern period. Yet while Western concepts of global geography by this period were informed by a much more complete map of the world, they continued to be based on constructed categories of spatial understanding.

The foundational construct of the Western system, for example, remained that of continental landmasses.

A mid-seventeenth-century “modern and completely correct map” of the entire world printed in Amsterdam by Joan Blaeu (1596–1673), a member of the family that helped to define mapmaking during the Dutch golden age.

The idea of continents goes back to ancient Greek navigators, who differentiated the lands found on either side of the Aegean and Black seas. Throughout the classical and medieval periods, the three known continents (Europe, Asia, and Africa) were conceptualized less as discrete landmasses than as connected portions of a singular world-island, the *orbis terrarum*. The discovery of the Americas forced a reconceptualization of global geography, as the “wheel of the Earth” came to be more cleanly divided into its original three parts, which, along with the Americas, now formed the “four quarters of the world.” Gradually, these “quarters” were reconceived as continents, which allowed the number of recognized major landmasses to increase. The Americas were eventually split in two, just as Australia and Antarctica were added to the continental roster, yielding the familiar sevenfold continental scheme.

The Continental Scheme

That Europe is still regarded as a continent shows both the manufactured nature of the scheme as well as the fact that it was devised by Europeans, who, not surprisingly, magnified the extent of their own homeland. In the original Greek formulation, Europe and Asia were considered separate landmasses because

they seemed to be all but sundered from each other by a series of seas and straits: the Aegean Sea, the Dardanelles, the Sea of Marmara, the Bosphorus, the Black Sea, the Straits of Kerch, and the Sea of Azov. The expansion of geographical knowledge eventually revealed that these two supposed continents were actually part of an undivided mass of land. Geographers thus competed during the eighteenth century to locate a suitable line of division. In due time, the Ural Mountains came to be accepted, even though this none-too-formidable range vanishes in the steppes of Kazakhstan. The separation of Europe from Asia thus violates the definitional basis of the continental idea, as continents are supposed to be more or less discrete masses of land largely separated from each other by bodies of water.

Even if Europe is classified merely as a segment of a Eurasian continent, as it occasionally is, the continental scheme remains an intellectual construction rather than an unproblematic reflection of the world’s underlying patterns of land and water. The actual building blocks of the earth’s surface, tectonic plates, fail to conform to the architecture of continents. In geological terms, India and Australia would have to be classified together, as both sit on the same plate. No consistent argument has ever been put forward, moreover, to support cataloging Australia as a small

continent rather than a large island—or Madagascar as a large island rather than a small continent.

Maritime Constructions

Oceans are no less capricious than continents. The supposedly separate oceans are interconnected by broad passages, as is clearly evident when one looks at a globe from the perspective of the South Pole. The boundaries between the oceans have been established by convention rather than discovered through empirical inquiry. In earlier periods, the maritime expanse had been conceptualized differently. During the eighteenth century, for example, European cartographers usually depicted “oceans” as arcs of water that wrapped around landmasses, potentially connecting distant lands. In Enlightenment-era atlases, an “Ethiopian Ocean” thus covered large expanses of what we now call the South Atlantic and southern Indian oceans, snaking around the contours of southern Africa.

From Continents to World Areas

Although the standard sevenfold continental scheme is still used in reference works, it has recently begun to lose favor in public discourse. Although the term *Asia* is still routinely employed, it now generally refers only to East, South, and Southeast Asia rather than to the formal continent. Both Southwest Asia (the Middle East) and North Asia (Siberia) have been, with little acknowledgment, excised from the Asian continent. Other continental labels are used with similar imprecision. “North America,” for example, sometimes refers to the United States and Canada, sometimes to those countries plus Mexico, sometimes to all three plus Central America, and sometimes to all of the areas mentioned above as well as the islands of the Caribbean.

Given these inadequacies, the continental scheme began to yield in the mid-twentieth century to a global architecture based on world areas. In the area studies framework, the fundamental geographical units are broad sub-continental blocks, ideally defined by shared cultural, political, or historical patterns. The

various world areas were constructed at different times and in accordance with different ideological or political designs. The term “Latin America,” for example, was put forward by French geographers during the period of Napoleon III, when France was seeking influence in the Western Hemisphere and wished to stress the commonalties of its Spanish-, Portuguese-, and French-speaking territories. The term was subsequently taken up by “Latin Americans” themselves, although it has never been without controversy.

The replacement of continents by world areas in the academic imagination was propelled by political events. During World War II, U.S. military planners concluded that the existing framework of global division was inadequate. As a result, the government commissioned an “ethnogeographical” board to remap the world. In the process, Asia was subdivided into East, South, and Southeast Asia, while Southwest Asia was appended to North Africa to form an expanded Middle East. Sub-Saharan Africa, the Soviet Union and its satellites, Western Europe, Latin America, North America, and Australia and the Pacific rounded out the roster of world regions. During the Cold War, the U.S. government funded area studies centers, while new area studies associations emerged to facilitate inquiry into regionally based cultural, social, and political formations. The newly minted world regional labels were sometimes taken up by political elites in the areas so designated. Southeast Asian leaders thus built ASEAN (the Association of Southeast Asian Nations), which they rigorously limited to the area that had recently been defined by Western scholars as “Southeast Asia.”

New Schemes of Geographic Construction

The end of the Cold War brought another round of geographical reconstruction. When the Soviet Union imploded, scholars were forced to grapple with the geographical positions of newly independent republics in the Baltic, Caucasasia, and Central Asia, as well as with those of former Soviet client states in Eastern Europe. At the same time, the entire area studies

A civilized nation can have no enemies, and one cannot draw a line across a map, a line that doesn't even exist in nature and say that the ugly enemy lives on the one side, and good friends live on the other. • Thor Heyerdahl

framework came under attack by scholars who objected to its rigid spatial divisions, its roots in Cold War geopolitics, or its general lack of theoretical rigor. By the turn of the millennium, many scholars were turning to an alternative form of global geographical construction based not on discrete regions but rather on webs of interaction, on the dispersed patterns of transnationalism, and on the widespread phenomenon of globalization.

Despite the rise of such non-bounded spatial concepts, alternative regionalization schemes at the global scale have retained salience. In the Cold War, a popular tripartite division of the globe, based on economic and geopolitical criteria, yielded the so-called First, Second, and Third Worlds. With the end of the Soviet Union, the Second World disappeared, undercutting the conceptual basis of that formula. While the First and Third Worlds linger in the public imagination, a more common gambit is to bifurcate the world into a wealthy “North” and an impoverished “South.” This construct, while polemically useful, is geographically imprecise, as certain countries in the southern half of the terrestrial landmass (Australia, Singapore, the United Arab Emirates, for example) are far more prosperous than some countries of the North (Albania, Ukraine, and Tajikistan, for example).

In short, while no single scheme of geographical construction is ever adequate for all purposes, most shed some light on the global order, whether of the past or the present.

Geography

The term *Geography* formally applies to an academic discipline (and a human construct) that encompasses study of the Earth's surface (Physical Geography), its inhabitants (Human Geography), and, more recently, its environment (Environmental Geography). Geographic data collected points to the "connectedness" of world systems, however, formulated in a unitary discipline to study the whole planet and all its denizens.

The Irish philosopher and theologian George Berkeley (1685–1753) laid out the notion of *subjective idealism*, in which the material world exists only through human perceptions. Many other Western writers have contested this notion, arguing that the external world had its own reality and that if humans ceased to exist then that world would still be there. In many ways the term *geography* as used in popular parlance and in academia still reflects that dichotomy.

Yet the English word *geography* (and its equivalent in many Western languages) is a critical reminder of humanity's place in the cosmos. There is *geography* (lower case) as understood popularly, meaning the way in which the world is laid out: "the geography of Latin America" or the "geography of cities in South Asia." (The term is still sometimes confused with the physical geography of a denoted area, but that usage is declining.) As well, there is *Geography* (upper case), an academic discipline that tries to describe and explain the phenomena of the surface of the Earth. If only the largely "natural" world of earth, air, and water is investigated, then there is *Physical Geography*, and if the human species is involved then,

unsurprisingly, there is *Human Geography*. Since the nineteenth century *Geography* has undertaken to interface both the physical and the human, and, since the late 1980s, the increasing public profile of "the environment" has brought forth studies labeled *Environmental Geography*.

Showing the World

How might it be possible to characterize the planet's geography without resorting to the kind of pixel-by-pixel count of different surface elements now made possible by computers and satellites? The statistics of land and sea cover deal with the immutable (continuous water bodies cover about 74 per cent of the surface) and the changeable, such as the cropland area at about 13.8 per cent, which had been close to zero only 10,000 years ago. The changes in land cover over time and space conform to a general model in which natural ecosystems are replaced with small-scale agriculture, then intensive agriculture, and finally urban-industrial zones. Throughout there have been attempts to protect some of the ecosystems as parks and reserves. One scientific way of describing this mosaic is to measure the ratio of solar-based energy flow to the energy flow directed by the human inhabitants. This ratio has shifted markedly in the last fifty years, with energy largely derived from oil being applied to the more intensive use of the Earth's surface and other resources. Thus more land was converted to crop production in the period from 1950 to 1980 than in the 150 years between 1700 and 1850. About 35 per cent of mangroves were lost, while water withdrawals from rivers and lakes doubled in the forty years between 1960 and 2000. Perhaps

10–30 per cent of mammal, bird, and amphibian species are threatened with extinction.

Can these data tell us anything more about the geography of the Earth? They certainly emphasize “connectedness.” Even if humans had never existed (or if they cease to exist, as no doubt one day they will) there are linkages and feedbacks that bring many processes into relationships with each other. Aerosols scattering just above the oceans metamorphose into cloud droplets that affect rainfall over adjacent continents; the temperature gradients of the South Pacific produce weather effects, and hence fires, over many parts of the Americas and Australia; a widespread cooling locks up water as ice, and therefore sea-level falls. In the most extreme interpretation of these ideas, James Lovelock (b. 1919) has proposed the Gaia hypothesis, that life created the global conditions for its perpetuation. But biological processes such as speciation have been essentially local, as have the amounts of recovery of land surface after glaciation or the sizes of landslides after earthquakes. There seems to be a case for differentiating between geographies resulting from interactions that occur in many places but do not coalesce (worldwide), and those in which any change can eventually affect the whole planet—as through alterations in solar energy input or the gaseous composition of the atmosphere—which we may call truly global.

Time and Place

One way of describing the development of the world’s geography is thus to chronicle through time the tensions between local processes and those that have been global. The great glaciations of the Pleistocene period, between 2.5 million years ago and 9640 BCE, had global significance since all the climatic belts of the planet shifted southward. Yet within that envelope, the concatenation of different species meant the development of variable ecosystems in various places: the savannas of tropical Africa were not the same as those of Venezuela, for example. Interaction between human communities after 9000 BCE brought new genotypes as agriculture

enforced selective breeding in the light of cultural demands, and new ecosystems as earlier ecologies were modified by human actions. The scale of many such activities expanded with trade and exploration even before the advent of steam power reduced the effects of distance and weather upon human economies and politics.

One major change was of course the application of fossil fuels via an iron-based technology that replaced the whole suite of cultural, economic, and environmental changes from about 1750 CE to 1900 CE, a period often labeled the Industrial Revolution. There was indeed “something new under the sun,” as the historian John R. McNeill has put it. This too was the time when a truly global effect became unequivocally manifest, as the greenhouse gas levels of the upper atmosphere began to rise in concert with the combustion of fossil fuels, the reduction in biomass, and the spread of irrigated wetlands. Since about 1950 CE all the trends of the post-eighteenth-century era have intensified and the terms *globalization* and *global village* are commonplace, although not all these recent economic and cultural trends actually affect the upper atmosphere or the entire world ocean and so are more accurately described as *worldwide*. Microelectronics far outpaces Puck in girdling the Earth. (Puck, a mischievous fairy in Shakespeare’s *A Midsummer Night’s Dream*, could circle the globe in forty minutes.) The humanization of the globe is now at a point where many people are anxious about the possibilities of sudden, irreversible, and certainly unpredictable change in weather patterns, climatic shifts, sea-levels, drought and flood frequency, water, food and energy security, mass migration, and conflicts of many kinds.

Modeling the World

So what has the human construct *Geography* said about all this change? Geographers existed under that very name in the classical Mediterranean and in the same function in dynastic China. Their role was to catalogue the known world of the time—as an act of knowledge-gathering in Muslim Alexandria

in the six centuries after 600 BCE, for example, or as a list of potential tribute-payers to the emperors of the Middle Kingdom in the fifteenth century CE. The advent of European and Chinese ocean-going vessels (with the Portuguese caravel as the Boeing 737 of its time) expanded the geographers' chief role to one of providing directions, especially in the form of maps. As with the material world, the alterations of the nineteenth century were profound: in keeping with Euro-American imperialism, for example, Geography reverted to its earlier though much expanded role of cataloguing the peoples, produce, travel routes, and religious-conversion potential of colonies, might-be colonies, and other dominions. At one spatial scale there might be list after list of the products of the factories of the Ruhr or of New England, at another an assessment of the geopolitical consequences of the Russian colonization of Siberia.

In academic Geography it was largely assumed that to name something was to capture its essence objectively, that to give it a number improved that objectivity, and that models based on analogies with studies in physics or derived from the theories of classical economics would explain patterns of distribution of human-made phenomena; for the nonhuman the explanatory methodologies of the appropriate sciences would be sufficient. The 1970s saw a considerable change with the injection of philosophical idealism. It was realized that the positioning of the human subject was vital. As agents, humans did not necessarily act as the rational players envisaged by classical economics; as investigators, geographers were not free from biases of upbringing, sources of finance, institutional pressures, gender prejudices and plain old orneriness. This led to the so-called cultural turn, in which the whole gamut of human culture might be called into play in order to discuss a geographical distribution or process. A factory might apparently be located at X because of the availability of low-cost transport, but in fact its proximity to several attractive golf courses tickled the fancy of the Japanese CEO. The insertion of theory was given another boost by poststructuralist philosophers such as Michel Foucault (1926–1984) in constructing archaeologies of ways of thinking and

writing about the world. They raised the question of sources of authority, a debate now overtaken by the prominence of the small screen of TV and computers as the crucial shaper of beliefs.

Given that Geography has dealt with both the human and nonhuman components of the planet, we might expect its practitioners to have been leading authorities in the waves of environmental concern that were present in the 1970s (the ecological crisis) and exist again now with climatic change at the forefront. That has largely not been the case. Like many other disciplines, Geography has had its specialists in that area, but has never taken to it in a grand manner. Indeed, for some it has usually been about “development,” and any reorientation towards a worldview constrained by limits of all kinds (including that of human numbers) has been resisted. Since the year 2000, outgrowths of its diversity have included two markedly different approaches. The first is the highly instrumental use of GPS (global positioning system) and GIS (geographic information system). The ability to locate any point within a few centimeters has spawned a whole set of geo-related industries concerned with resource use, planning, environmental inventory, and spatial imagination. The second growth is almost diametrically opposite: the personal construction of an interior world from a fragmentary outer cosmos seems to have been pioneered by the literary figure W. G. Sebald (1944–2001) and has been carried on (in the United Kingdom, at least) by people who have attracted the label “psychogeographers.” One of them has imitated Sebald’s journey down the coast of East Anglia with a foot patrol of London’s circumferential M25 motorway.

There is a world out there and there are models of that world in our heads and in our media. In a mirror-like fashion, Western thought has often relied on dualities. The idea that humans are totally exceptional has created gaps between human societies and valuation of the rest of the cosmos as a mere theatre for their actions. But global linkages show us that is not the case: we are “all netted together,” as Charles Darwin wrote in a notebook of 1838. The divergences in Geography suggest that there is still

some way to go in formulating a unitary discipline of the whole of the planet and all its denizens.

German Empire

From about 1884 to 1919, the German Empire colonized areas in Africa (mostly) and Oceania. Although historians comparing Germany's colonial policies have recognized origins of Nazi ideology in use in Africa, recent studies approach such generalizations with caution. Germany's paternalist rule incorporated indigenous legal systems, provided security and stability, and sponsored anthropological studies that still figure as important reference works today.

Any discussion of the impact of the German Empire on world history has to begin with an apparent paradox: despite its short duration, approximately from 1884 to 1919, the German Empire has received historical attention that parallels that given other European empires whose colonial possessions were larger and longer lasting.

Chronology of Empire

In a narrow chronological sense, German colonialism can be divided into four phases: 1884–1890, 1890–1906, 1906–1914, and 1914–1919. In 1884 the German government, under Chancellor Otto von Bismarck, annexed areas in Africa and the Pacific Ocean. Bismarck was a reluctant colonialist who attempted to place the estimated high administrative costs of these colonies on a number of chartered companies. The majority of these attempts, however, failed. Eventually German authorities assumed administrative duties in the colonies. Increasing governmental involvement in colonial affairs led to the establishment of the Colonial Division within the German Foreign Office by

1890, which marks the beginning of the second phase of German colonialism. Four years later this division gained more independence through the appointment of a colonial director. Despite this appointment, the Colonial Division remained the stepchild of German foreign policy because few German civil servants desired colonial appointments. The prestige of the Colonial Division suffered further in the selection of its directors. Chosen less for their colonial expertise than for their loyalty to the Imperial Court, the directors had a high turnover rate and provided little stability for the division.

Violent indigenous uprisings in the German colonies of East Africa and Southwest Africa between 1904 and 1907 brought the colonies to broad public attention. Several hundred German settlers lost their lives, and thousands of German soldiers found themselves dispatched to the colonies in an attempt to regain control. Increasing violence and expenditures made the German colonial endeavor a favored target of the German Parliament (Reichstag). When, in late 1906, Chancellor Bernhard von Bülow requested further appropriations for the African colonies, a majority of delegates rejected his request. Disappointed, Bülow dissolved the Reichstag and called for a new election. The press deemed the elections “Hottentot elections” (Hottentot was a rather derogatory name for the Herero Nama population of German South Africa) due to the colonial connotations. Bülow's broad coalition ultimately emerged from the election victorious to put forward a detailed program of colonial reform. This program involved the creation of an independent Colonial Office led by a secretary of state, improvement of colonial civil servant

Under the leadership of the first German emperor, Kaiser Wilhelm I (1797–1888), and with the aid of Otto von Bismarck, Germany was poised to expand its empire.

education, and economic self-sufficiency in the colonies. Bühlow's choice for colonial secretary of state was Bernard Dernburg, a prominent banker.

The so-called Dernburg era ushered in the third phase of German colonialism, which stood under the rubric of "scientific colonialism." In classical fashion Dernburg envisioned using colonial resources for metropolitan development. At the same time he sought to improve the lives of Africans and Pacific Islanders through the benefits of "higher" German civilization. In practice this meant improving infrastructure, especially railways for the African colonies, and increasing German economic investments. Dernburg's program also invited establishment of colonial schools designed to train colonial civil servants (the most important of these schools was the Colonial Institute in Hamburg) and scientific stations throughout the colonies to further economic development. When Dernburg stepped down from his office in 1910, his two successors, Friedrich von Lindequist (1910–1911) and Wilhelm Solf (1911–1918), continued his program.

The fourth and last phase started with the outbreak of World War I. This war prevented any long-term success of Dernburg's program, however, and ended German colonialism. Blockaded by the British Royal Navy, the German government was unable to assist its colonies. Nor did Germany ever intend its colonies to become a major battleground. Colonial troops, aptly called Protective Forces (*Schutztruppen*), existed only on the African continent. Hastily assembled settler militia and indigenous police forces proved no match for Australian, Japanese, and New Zealand contingents who occupied the German Pacific colonies by the end of 1914. In Africa the fighting continued beyond that time, although Togo, the smallest of the German African colonies, surrendered after only three weeks. By 1915 German Protective Forces surrendered to South African troops in southwest Africa. A year later fighting ceased in Cameroon. After 1916 only East Africa remained at war. Here a small, unintentionally racially integrated, rag-tag army continued a guerrilla campaign against a combined force of Belgian, British, and Portuguese soldiers until the end of the war. The leader of the East Africa campaign, Lieutenant-Colonel Paul von Lettow-Vorbeck, returned to Germany to a hero's welcome and was highly decorated for preventing the deployment of Allied troops to the western front in Europe. His loyal colonial *Askaries* (designation for indigenous soldiers or policemen in German East Africa) fared much worse because the government withheld soldiers' wages until the 1960s. The Treaty of Versailles in 1919 sealed the fate of German colonialism because all the German colonies became mandates under the newly formed League of Nations.

Comparative Geography of the Empire

With the exception of a small 643-square-kilometer enclave on the Chinese mainland administered by imperial naval authorities, most of Germany's colonies were located in Africa and Oceania (islands of the central and south Pacific). Most of these colonies, including Cameroon, East Africa (today's Tanzania),

The Reichstag building, home of the German Empire's parliament from 1894 to 1933.

Southwest Africa (today's Namibia), and Togo, were located in Africa. In Oceania the German Empire made up the second-largest colonial presence, after Great Britain. Germany occupied the northeastern corner of New Guinea, which is today part of Papua New Guinea, and the surrounding Bismarck Archipelago, as well as the northern Solomon Islands. Most annexations were made after the year 1884, with only a fraction of annexations—Micronesia and the western isles of Samoa in Oceania, as well as a small increase of existing colonies in Africa—made during the so-called New Course policy that followed Bismarck's dismissal. All in all, Germany's colonies contributed little to its economy. Investments in the colonies rarely accounted for more than 1 percent of German overseas trade, mainly because the colonies were deficient in resources. Southwest Africa provided some copper and diamonds after 1906, but the bulk of the economy remained tropical agriculture. Agricultural products could be quite diversified

in Africa, including such products as cotton, rubber, and even ostrich feathers. In the Pacific, on the other hand, agriculture was closely tied to coconut plantations.

The differences in resource exploitation aside, historians recently proposed a closer understanding of variations in the German administration in Africa and the Pacific Islands. Frequent military campaigning and crackdowns on indigenous people were the norm in Africa and commanded considerable attention in the national and international media. Most telling of German administrative abuses are the operations against the Herero and Nama people in Southwest Africa (1904–1907) and the Maji-Maji rebellion in East Africa (1905–1907). Southwest Africa was Germany's lone settlement colony (the German presence in the other colonies never surpassed a few hundred settlers) in the empire and attracted several thousand ranchers. Already strained relationships with the cattle-herding Herero further deteriorated when

an introduced plague decimated the herds. German authorities used herd reductions as a welcomed excuse for further land alienation. When open warfare erupted by 1904, German Protective Forces brutally crushed the Herero. Lieutenant General Lothar von Trotha issued the famed extermination decree, ordering his troops to fire upon every Herero, regardless of age or gender, who chose not flee to the desert. Although Berlin officials soon deemed Trotha's policy excessive, it proved frighteningly effective. By 1907 the Herero population had been reduced by 75 percent. When the Nama, traditionally enemies of the Herero, rose up against the German overlords, they fared little better; their numbers were reduced by 50 percent.

For comparative purposes the German policies of extermination in Africa were in contrast to German administration of the Pacific Islands. Traditionally historians recognize in the German African colonial policy the origins of Nazi expansionism and extermination. Recent studies, however, are cautious about such generalizations. Violence and abuses did occur in the Pacific, but they were the exception rather than the rule. Indeed, the relative remoteness of the Pacific colonies allowed for a number of administrative experiments. Governors ruled for unusually long periods in German New Guinea and Samoa, thus providing stability and continuity. Their paternalist rule incorporated indigenous language and legal patterns. They also encouraged anthropological studies in the Bismarck Archipelago, Micronesia, and Samoa, which sparked ethnographic (cultural study) monographs that still figure as important reference works today.

Contemporary Studies in German Colonialism

Traditionally studies of German colonialism have emphasized diplomatic history. Brisk attempts to gain a colonial "place in the sun" for Germany are frequently cited as one of the main conflicts leading to World War I. The best-studied examples of such conflicts are the two Morocco crises (1905 and 1911) in Africa

and the tangle over the Samoan Islands in the Pacific (1889–1899). The Samoa conflict would ultimately result in a partition of the Islands, the western isles became the protectorate of German Samoa.

The German Empire has gained importance among scholars in the postcolonial realm. Although "Orientalist" scholars—who believe in the existence of a clear link between scholarship and colonialism—argue that the German Empire did not last long enough for German writers to develop a clear link between scholarship and colonial administration, recent investigations have indicated otherwise. Literary scholars argue that an absence of colonies did not prevent Germans from developing "colonial fantasies" that formed templates for future colonial rule. In essence, such "colonialism without colonies" placed Germany on an expansive path similar to that of other European powers.

Equally revealing are contemporary studies of the development of German anthropology during the imperial age. Shunning simple-minded explanations that anthropology and colonialism went hand in glove, these studies reveal the Germans' intense interest in non-European peoples. Many German anthropologists perceived artifacts as important historical sources of information about so-called non-literate peoples of the world. These intellectuals argued for storage of these artifacts in museums specifically designed for this purpose. Consequently, German anthropological museums developed into premier institutions in the world. Their holdings surpassed those of similar museums in England and France, both countries with far greater colonial empires. Similarly, Germans developed a popular interest in *Völkerschauen* (commercial ethnographic exhibitions) that brought the empire home to the public. In short, despite its brevity, recent studies have rediscovered and reassessed the German Empire. Far from being marginal, German colonialism in Africa and the Pacific has important implications for world historians.

Glass

Glass made from melted sand was produced in ancient Egypt but long remained scarce and unusual. Over time hotter fires made glass manufacture easier, and as it became cheaper and more abundant glass started to change human life profoundly: blowpipes shaped hollow vessels and other containers; flat window panes made houses warmer and better lighted; and ground-glass lenses for telescopes and microscopes enlarged the known world enormously.

Natural glass in the form of obsidian—a hard, sharp-edged natural glass formed from rapidly cooled volcanic lava—was a key material for the human tool kit as a source of sharp blades for knives and spear and arrow points. It was also an important prehistoric trade item in the Mediterranean basin, Europe, Mexico, North America, and Oceania. Anatolia was a key source of obsidian for Mesopotamia beginning about 8000 BCE.

Development of Human-Produced Glass

Human-produced glass in the form of glass beads was probably first made in Egypt and Mesopotamia in about 3500 BCE. Hollow glass technology, which produces functional vessels, dates to about 1700 BCE in Mesopotamia and Egypt, and glass was beginning to be produced in northern Europe, Greece, and China at about this time as well. Glassblowing, a far more efficient method for producing vessels, was developed in the Babylon region around the time of the BCE/CE transition.

The Romans were the first major exploiters of and innovators in glassmaking technology. They used molds for blown glass, developed flat glass suitable for windows, and spread the use of glass throughout the empire and beyond. Much wider use of glass for windows followed refinements in production techniques by the Germans in the eleventh century and by the Venetians in the thirteenth century—techniques that led to higher quality and more attractive sheet glass. Mirrors came into widespread use in the eighteenth century following innovations in France in 1688.

Glass became a major industrial product during the industrial revolution when scientific research produced high quality optical glass and mass production methods. These refinements continued in the twentieth century with glass products becoming cheap, household goods.

Uses of Glass

The role of glass in world history is perhaps best understood as but one example of a common pattern in world history in which the generation of new knowledge leads to significant innovations and the embedding of a richer understanding in new or improved objects. These objects, which anthropologists call material culture, if they are useful, in demand and relatively easy to produce, are often disseminated in huge quantities. These objects then change the conditions of life and may well feed back into the possibilities of further exploration and innovation. This can happen in two ways: (1) by generating the wealth that enables more effort to be applied to the generation of new knowledge; or (2) by providing better tools for

Roman antique glass. Romans, the first major innovators in glassmaking technology, used molds for blown glass. Library of Congress.

improved understanding. This pattern of innovation and change has occurred in many spheres of life. The pattern is enduring when objects are widely disseminated and it can be a cumulative process.

There have been five major uses of glass around the world over the course of history, and only a few were universal before 1850. Glass has long been used for decorative purposes in the forms of glass beads, counters, toys, and jewelry in many cultures across Eurasia. For this purpose, glass blowing is not absolutely required, nor does this use have much influence on thought or society, but rather on luxury goods and aesthetics. Basically glass is a substitute for precious stones.

Another common use is for vessels, vases, and other containers. Before 1850 this use was largely restricted to the western end of Eurasia. Glass was little used for vessels in India, China, and Japan, where pottery was the primary medium. In the Islamic world and Russia, the use of glass declined dramatically from about the fourteenth century with the Mongol incursions. The great developers of glass for vessels were on the Italian peninsula, first the Romans, and later the Venetians.

A third major use of glass was and is for windows. Until the late nineteenth century, window glass was found only at the western end of Eurasia. Before that time, China, Japan, and India hardly made use of glass for windows, using bamboo and paper shades instead. The most dramatic development of window glass was even more limited, taking place mainly in Europe north of the Alps.

The fourth major use comes from the reflective capacity of glass when silvered. The development of glass mirrors covered the whole of western Europe,

but largely excluded the Islamic world. Glass mirrors were less popular in India, China and Japan.

The final major use of glass is for lenses and prisms and in particular their application to human sight in the form of eyeglasses. The concept of the light-bending and magnifying properties of glass was probably known to all Eurasian cultures, and was certainly known to the Chinese by at least the twelfth century. Yet only in western Europe did the practice of making lenses really develop, mainly from the thirteenth century. This coincides precisely with the dramatic new developments in optics and mathematics, which fed into all branches of knowledge, including architecture and painting.

Glass in World History

The reasons for the differential development of glass across the globe are largely accidental—differences in climate, drinking habits, availability of pottery, political events, and many other localized situations. The reasons have little to do with intention, planning, or individual psychology, nor are they the result of superior intellect or superior resources. Glass did not directly cause deepening of knowledge in Renaissance Europe and during the scientific revolution of the seventeenth and eighteenth centuries, but it did contribute to these movements by providing new scientific instruments such as microscopes, telescopes, barometers, thermometers, vacuum flasks, and many others. At a deeper level it literally opened people's eyes and minds to new possibilities and turned the Western world from the aural to the visual mode of interpreting experience. The collapse of glass manufacturing in the Islamic world and its minor role in

India, Japan, and China made the type of knowledge revolution that occurred in Western Europe impossible in those places.

Without glass instruments, such sciences as histology, pathology, protozoology, bacteriology, molecular biology, astronomy, physics, mineralogy, engineering, paleontology, vulcanology, and geology could not have developed. Without clear glass there would have been no laws about gases, no steam engine, no internal combustion engine, no electricity, no light bulbs, no cameras, and no television. Without clear glass, scientists could not have seen bacteria, and there would have been little understanding of infectious diseases.

Chemistry also depends heavily on glass instruments. For example, without glass there would have been no understanding of nitrogen and so no artificial nitrogenous fertilizers. Consequently, much of the agricultural advances of the nineteenth century would not have occurred without glass. As for astronomy, there would have been no way of demonstrating the structure of the solar system, no measurement of stellar parallax, no way of substantiating the conjectures of Copernicus and Galileo. These findings initiated a line of inquiry that, through the application of glass instruments, has revolutionized the understanding of the universe and deep space. And in biology, without glass we would have no understanding of cell division (or of cells), no detailed understanding of genetics, and certainly no discovery of DNA. Without eyeglasses, a majority of the population in the Western world over the age of fifty would not be able to read this article.

The role of glass in history goes far beyond science. Without mirrors, lenses, and panes of glass the artistic developments of the Renaissance would not have occurred. The new understanding of the laws of optics, along with the new accuracy and precision in painting were largely dependent on glass instruments of various kinds. The divergence of world art systems in the period between 1350 and 1500 is impossible to conceive of without the development of fine glass, which only occurred at that time in Venice.

A stained-glass window depicting St. Francis of Assisi. Photo by Chris Howell, 2003.

Glass is not just a tool to aid in understanding the world, but also a tool to enhance comfort, efficiency, and health. Glass lets light into interiors and is a hard and cleanable surface. This was one of its attractions to the fastidious Romans as a raw material for vessels, and likewise for the Dutch—in whose country the use of glass developed most. Transparent glass lets in light so house dirt becomes more visible. The glass itself must be clean to be effective. So glass, both from its nature and the effects it has, makes hygiene easier to achieve. And, glass not only altered the private house, but in due course transformed shops, which began to arrange their merchandise behind glass windows.

Glass also helped transform agriculture and knowledge about plants. The use of glass in horticulture was not an invention of the early modern Europeans. The Romans had used forcing houses and protected their grapes with glass. This Roman idea was revived in the later Middle Ages, when glass pavilions for growing flowers and later fruit and vegetables began to appear. As glass became cheaper and flat window glass improved in quality, greenhouses improved the cultivation of fruit and vegetables, bringing a healthier diet to the population. In the nineteenth century, glass containers made it possible for seeds and plants to be carried safely on long sea journeys from all over the world to add variety to European farms and gardens.

Mounds of glassware stacked precariously, are ready for sale in the weekly Athens street-market. Photo by Karen Christensen.

Among other innovations that altered daily life were storm-proof lanterns, enclosed coaches, lighthouses, and street lighting. Thus travel and navigation were safer and easier. The sextant requires glass and the precision chronometer cannot be used at sea without glass. Glass bottles created a revolution in drinking habits by allowing wine and beers to be more easily stored and transported. Glass even affected what humans believed (stained glass) and how they perceived themselves (mirrors).

Thus, at first through drinking vessels and windows, then through lanterns, lighthouses, greenhouses, telescopes, and microscopes, and later through cameras, televisions, and computer screens, the modern world built round glass emerged.

Global Commons

The term *global commons* refers to the Earth's natural resources that fall beyond the jurisdiction of any state, such as the oceans, the atmosphere, and outer space—and, since the enactment of the Antarctic Treaty of 1959, Antarctica as well. The treaty totally demilitarizes the continent, freezes the claims of any state, and ensures freedom of scientific investigation. As of 2009 the treaty includes forty-seven signatories.

The global commons are domains that lie beyond the exclusive jurisdiction of any state, but which may be used by all states and their nationals. Among areas traditionally considered as global commons are the world's oceans, the Antarctic, the atmosphere, and outer space, all of which today are governed by international regulatory regimes.

Oceans

The oldest recognized commons are the world's oceans. Ocean space covers 71 percent of the Earth's surface, touches 150 states, and serves as a main conduit for international trade and commerce, as well as a vast storehouse of food, mineral, and energy resources. The 1982 United Nations Convention on the Law of the Sea, which in 2009 has 153 state parties, is the framework instrument for managing the ocean commons. Its 440 provisions incorporate generally accepted principles relating to activities on, over, and under the world's oceans. With respect to offshore delimitation, the convention adopts a 12-nautical-mile territorial sea, over which the coastal state enjoys all rights of sovereignty. The convention creates a new delimitation, the 200-nautical-mile

exclusive economic zone (EEZ), which establishes offshore state jurisdiction over the exploration for and exploitation of natural resources. It provides objective criteria for delineating the outer limits of the continental shelf and the high seas, and it articulates certain freedoms for use of the high seas, including vessel navigation, aircraft overflight, and the rights to fish, lay pipelines and cables, and conduct marine scientific research. The convention also establishes the right of vessels (and aircraft) to pass unimpeded through international straits, as well as obligations for all states to protect the marine environment and to regulate scientific marine research. The most difficult issue negotiated in the convention concerned deep seabed mining and who has the right to mine manganese nodules from the deep seabed—states with the technology to do so or an international regulatory body? The convention establishes an international organizational structure to regulate future deep seabed exploitation.

The Antarctic

The Antarctic commons encompasses the massive ice-covered continent surrounded by the Southern Ocean. Antarctica approximates the size of the United States and Mexico combined (14 million square kilometers), and is the highest, windiest, most desolate continent. It is also the world's largest desert (in terms of precipitation), yet paradoxically contains 70 percent of the world's fresh water frozen in its massive ice cap. Argentina, Australia, Chile, France, New Zealand, Norway, and the United Kingdom claim territory in the Antarctic. Following the successful International Geophysical Year during 1957–1958, these seven

We must become the change we want to see. • **Mohandas Gandhi (1869–1948)**

states, along with Belgium, Japan, South Africa, the Soviet Union, and the United States, agreed that preserving international cooperation in the Antarctic was essential. In 1959, the governments of all twelve nations negotiated the Antarctic Treaty, which in 2009 has forty-seven parties. This agreement totally demilitarizes the continent, freezes the claims, and ensures freedom of scientific investigation. Additional agreements for the Antarctic have been negotiated, including the 1964 Agreed Measures for the Conservation of the Antarctic Fauna and Flora, the 1972 Convention for the Conservation of Antarctic Seals, the 1980 Convention for the Conservation of Antarctic Marine Living Resources, a 1988 Convention on the Regulation of Antarctic Mineral Resource Activities (which never entered into force), and the 1991 Environmental Protection Protocol to the Antarctic Treaty. Serious problems still confront the Antarctic commons, among them increasing shipborne tourism to the region, the accelerating depletion of fisheries in circumpolar seas, and the effects of global warming resulting in disintegration of Antarctic ice shelves.

The Atmosphere

The atmosphere includes the troposphere (where weather patterns begin), as well as the stratosphere (where the ozone layer is located), the mesosphere, and beyond. The atmosphere provides virtually limitless sources of oxygen, carbon dioxide, and nitrogen essential for all life, as well as the water needed for living resources. At the same time it shields the Earth from ultraviolet radiation, cosmic rays, and meteors.

Three manmade threats to the atmosphere required creation of special regimes. The first of these occurs in the stratosphere and relates to human-released chlorofluorocarbons (CFCs) that react photochemically, thereby eroding the ozone layer. This process permits more intense ultraviolet radiation and greatly amplifies the risk of skin cancer for larger numbers of people in the Southern Hemisphere. Reaction to this threat in 1985 produced the Vienna Convention for the Protection of the Ozone Layer, but this instrument

does not contain specifics on how to arrest ozone depletion; it merely calls for action. Consequently in September 1987, governments negotiated the Montreal Protocol on Substances that Deplete the Ozone Layer, which sets out a schedule for progressively phasing out CFCs.

A second atmospheric threat concerns global climate change. Human activities—most importantly deforestation and the burning of fossil fuels such as coal, oil, and natural gas—are known to be altering the atmosphere's composition and contributing to global warming, although uncertainty still surrounds its severity or future effects. These changes cause glaciers and polar ice caps to melt, thereby raising sea levels and threatening islands and low-lying coastal areas. The international response to the climate change threat came in the U.N. Framework Convention on Climate Change, adopted at the Rio Summit in 1992. This instrument establishes a process for voluntary reduction of greenhouse gas emissions. In December 1997 the Kyoto Protocol was negotiated to legally commit industrialized states to reduce greenhouse gas emissions. Final negotiations on the protocol in 2001 require industrialized states to reduce their combined annual greenhouse gas emissions by 2012 to 5.2 percent below the levels measured in 1990.

A third threat to the atmospheric commons is airborne transnational pollution. The air serves as a medium for pollutants, most notably transnational acid precipitation from the United Kingdom over Scandinavia and from the United States over Canada. In 1979 the International Treaty on Long-Range Transboundary Air Pollution (LRTAP) was negotiated, which remains the preeminent attempt to regulate transboundary air pollution. At least eight protocols have been negotiated to curb specific pollutants, such as sulfur emissions and nitrous oxide.

Outer Space

The final global commons is outer space, which extends beyond the Earth's atmosphere. As humans seek to use this region, the need for regulating it grows. Special international agreements now comprise a

legal regime for managing the outer space commons. The main agreement is the 1967 Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space. This agreement sets out core duties for states using outer space. Among these are the stipulation that exploration and use of outer space shall be carried out in the interests of all countries; outer space shall be free for exploration and use by all states; outer space is not subject to national appropriation by claim of sovereignty; no weapons of mass destruction may be placed in orbit or on celestial bodies; the moon and other celestial bodies shall be used exclusively for peaceful purposes; and states shall be liable for damage caused by their space objects.

Other major space law instruments include the 1968 Convention on the Rescue and Return of Astronauts and the Return of Objects Launched into Space, the 1972 Liability for Damage Caused by Space Objects Convention, and the 1975 Convention on Registration of Objects Launched into Outer Space. A fifth accord, the 1979 Agreement Governing the Activities of States on the Moon and Other Celestial Bodies (the Moon Treaty), has attracted few parties and no space-faring state.

The industrial revolution profoundly changed how the global commons are used, particularly in terms of resource exploitation and environmental degradation.

If the oceans, Antarctica, the atmosphere, and outer space are to provide future benefits for all humankind, governments will have to cooperate more closely to regulate and enforce the legal regimes created for their protection and conservation.

Globalization—Historical Perspectives

The web of human communication spread slowly and sporadically beginning with the earliest foraging populations in East Africa, but people remained unconscious of their global reach until European navigators sailed across the Pacific after 1492. Social, economic, and cultural impacts ensued as technologies and travel advanced globalization during the Industrial Revolution and into the twentieth-first century.

Ever since humans achieved their distinctive powers of speech and started to expand beyond the savanna lands of East Africa, contacts with neighbors kept separate bands in occasional touch with one another; and exchanges of genes allowed them to remain a single species even after spreading entirely around the globe. A slender global web of communication sporadically interrupted in remote locations—sometimes for centuries or longer—continued to unite humankind. But as long as people knew nearby neighbors only, no one was conscious of the global reach of the human web.

Even after about 100 BCE when peoples as far apart as the Chinese, western Asians and Europeans became aware of one another through military expeditions and trade, their consciousness remained restricted to Eurasia. Centuries of improvement in transportation gradually expanded the reach and intensity of contacts within the Old World, and parallel though less capacious linkages also developed in the Americas. The spread of bows and arrows from Eurasia to the Americas, beginning about 100 CE, and still spreading among the Caribbean islands when Columbus arrived in 1492, is the firmest evidence we

have of how the two systems sometimes interacted, at a time when bows and arrows were still unknown in Australia and islands of the Pacific.

Globalization only became conscious when European navigators discovered America, and then sailed across the Pacific between 1492 and 1519. At first only a few were aware of the new contacts Europeans ships thus inaugurated. The news spread rapidly among the literate classes within Europe, thanks to printing and mapmakers; elsewhere reaction was slower and less enthusiastic.

The most significant effect, initially, was the transfer of infectious diseases from disease-experienced populations of Eurasia to previously isolated peoples, who lacked inherited resistance to the new infections. They therefore suffered disastrous die-offs when exposed to a series of lethal diseases like smallpox, influenza, and measles. Small islands were wholly depopulated; Amerindians in Mexico and Peru suffered something like 80 percent die-off within the first 120 years of exposure; and comparable losses occurred in Pacific islands and among previously isolated peoples elsewhere.

Colonists from Europe and slaves from Africa soon started to supplant the demoralized and diminished Amerindians. A lengthy process of frontier expansion at the expense of Indian peoples ensued in both North and South America, ending in the United States, according to the official census, only in 1890. The rise of the United States and other American nations like Brazil, Mexico, Argentina, and Canada radically altered the older Eurasian balance of power and population. This was the principal change resulting from the first phase of globalization.

As infectious diseases reached their climatic limits and local human populations developed similar levels of resistance to them, and as doctors simultaneously learned how to control infections with vaccination and antibiotics, epidemics ceased to play such a significant role in human affairs. Nonetheless, globalization continued to upset existing social arrangements everywhere, mainly through increasing economic and cultural impacts.

That in turn depended on the rapid improvement in transport and communication that arose from increasing reliance on machines and inanimate energy, which historians often refer to as the Industrial Revolution. Coal-burning steam engines were the first to power factories (1785), steamships (1807) and railroads (1825). In due course, oil and electricity supplemented and often supplanted coal as a preferred source of power. Instantaneous communication was inaugurated with the electric telegraph (1837). Telephone (1876), radio (1895), movies (1895), airplanes (1903), TV (1936), and computers (1946) followed in rapid succession, each affecting few at first, but rapidly expanding their scale of operation and altering the daily lives of a majority of humankind.

The resulting sudden assault on older habits and routines is what globalization has come to mean in recent years. In economics, its principal manifestation was a vast expansion of international trade and especially the spectacular rise of China as an exporter of manufactured goods after 1978. Cheap, often excellent consumer goods made in China flooded into the United States and other countries, sometimes displacing local manufacturers. The banking and financial crisis that began in the United States in 2008 and soon spread to the rest of the globe intensified the pressure on the U.S. and European manufacturers. The bankruptcy of General Motors and Chrysler signaled the seriousness of the crisis for the United States. How it will be resolved remains uncertain.

Though globalization may be blamed, trying to exclude foreign imports is unlikely. Costs would be very high and beyond all calculation. Effective global

Yoshiiku Ochiai, woodcut (1860). A Russian woman plays the flute for a British man holding a rifle. Technologies and travel advanced globalization during the Industrial Revolution, resulting in social, economic, and cultural impacts.

regulation and deliberate economic management is even more unlikely. Accordingly, global competition will probably continue to challenge established economic relationships—just as it has throughout the past, but now with unprecedented speed and force.

Culturally a similar competition arose as movies, then TV and recorded popular songs, began to influence human behavior and expectations. Hollywood blockbusters in from United States and Indian movies mostly produced in Mumbai (Bombay), achieved the widest circulation beyond national borders. When poor peasants and recent migrants living in urban slums encountered the wealth, luxury, and sexual display flaunted by movie stars and pop singers, discontent with their own harsh circumstances tended to intensify. Young people in particular often rebelled

It has been said that arguing against globalization is like arguing against the laws of gravity. • **Kofi Annan (b. 1938)**

against the customs and norms their parents sought to transmit to them.

But as local customs and traditions were thus weakened, a powerful counter current of religious reaction arose, especially in Muslim lands, energetically aimed against the “Great Satan” of American popular culture. Terrorist attacks resulted, most notably the destruction of the World Trade Center towers in New York on September 11, 2001, whereupon the American government declared a “War on Terror” and invaded Afghanistan, thereby inaugurating hostilities that still continue in 2010.

Economic setback and the War on Terror thus join together to confront the American people and their government with unsolved problems that seem sure to persist for a long time. It therefore appears that globalization can hurt poor and rich alike, intensifying

the pace of social change around the globe to or beyond the breaking point when ruthless violence takes over.

Globalization—Modern Conceptions

Discussions about the pros and cons of globalization can be clarified by analyzing the term as a process or a phenomenon. As a process, globalization is not historically universal but can proceed in different ways at different times. What defines globalization is not the end state but a series of actions: reducing the isolation of territorially defined communities, and increasing the interaction and variety of contacts between them.

The first step toward a clearer view of *globalization* is to distinguish the word, as a noun used to describe a phenomenon or an existing condition, from the use of *globalize*, a verb implying a process. In the former example, we witness globalization to the extent that consumer goods from all parts of the world are now available in the market shelves of the richest countries. Similarly, in practically every corner of the globe one can find islands of consumption similar to those enjoyed in the rich countries. Globalization has drastically reduced the time these transactions take, and dramatically improved the ease with which they are arranged. We now can travel practically anywhere in the world in less time that it would have taken to go from the capital to a provincial town a century ago. It is also possible to phone or obtain information on faraway regions in literally seconds.

If we use the term *globalization* in this way, the Spanish sociologist Manuel Castells (2000) contends that we are living through a dramatic transformation into a global economy distinct from the “world” economy born in the sixteenth century. Yet Paul Hirst and Grahame Thompson (1999), in their

book *Globalization in Question*, offer evidence indicating that the current process of global interconnection is much less dramatic than what occurred in the late nineteenth and early twentieth centuries. Whatever the specific years of its beginning, there is no question that certainly beginning in the mid-nineteenth century, and then following World War II, the world has seen an unprecedented degree of globalization, especially as we include all the new forms of noneconomic contact (e.g., tourism and the Internet).

If we prefer to understand the concept by using *globalize*, the verb, then we can speak of the thickening of contacts between previously isolated regions, and the facilitation and institutionalization of such flows. In this way, “global” would not refer exclusively to processes involving the whole world, but the integration of known areas of possible interaction. As such, globalization has occurred in various other historical periods. Empires such as the Roman, Chinese, and Ottoman, as well as the Islamic community by the fifteenth century, could be perceived as engaging in a process of globalization. One could argue that the initial migration of hominids from Africa and their subsequent colonization of the Earth was the first example of this process, as was the network of trade routes along the Silk Roads between China and the Mediterranean, which began in earnest during the second century BCE. The degree of European expansion in the fifteenth century would be another, as would the creation of subsequent empires through the nineteenth century. The revolutions in communication and transportation culminating in cheap airfares and the Internet are thus merely means in the latest phase of globalization.

Measuring Globalization

Precisely because it is so apparently ubiquitous, measuring the extent of globalization has not been easy. The development of international trade has been the most immediate (or most visible) phenomenon associated with it, but money, in and of itself, has come to play an arguably even larger role than does the transfer of material goods. Labor, while still subject to much greater control than capital, moves transnationally while international tourism now involves millions of people yearly. The ubiquity of American culture is already a cliché, but it is also possible to eat sushi, drink Beaujolais, and buy curry in any metropolitan center.

Perhaps the most often used figures involve the increases in the global exchange of goods and money. In the 1960s trade accounted for one quarter of the global production of goods and services. By the

twenty-first century international flows accounted for roughly half of these. Cross-border trade became so prevalent that the world actually traded more than it made each year (accounted for by goods moving back and forth across borders during production and because of transshipments). More spectacular was been the growth of global finance. Foreign exchange dealings totaled US\$15 billion in 1973, but in 2001 the total was nearly one hundred times as much. Foreign direct investments tripled during the 1990s to equal nearly US\$750 billion dollars and represented the lifeline for many economies. The United States itself financed its government and commercial deficits by relying on a global community willing and able to purchase its debts. In 2010, as governments, businesses, and individuals attempt to recover from a global financial crisis, it has never been clearer how economies worldwide are inextricably linked.

Map showing the telegraph lines in operation, under contract, and contemplated to complete the circuit of the globe in 1869, four years after the formation of the International Telegraph Union.

People have accused me of being in favor of globalization. This is equivalent to accusing me of being in favor of the sun rising in the morning. • **Clare Short (b. 1946)**

But contemporary globalization is different from previous epochs, precisely because it involves many other forms of contact other than exchange of goods and services. Migration, for example, obviously played a huge role in the nineteenth century, but in the twenty-first, it has become even more critical to the survival of both sending and receiving countries. Three major networks seem to exist: from Africa and eastern Europe to western Europe, from Latin America and China to the United States, and from Southeast Asia to the Persian Gulf. There are also smaller cycles in western Africa and South America, and within countries. It is difficult to measure much of the migration as it is illegal, but estimates for the 1990s include 25 million for politically induced migration and 100 million for economically or socially induced migration. By 2005 a United Nations estimate put the total figures worldwide at 185–192 million. Tourism is an even more recent phenomenon and one that has shifted the way many people view other countries and cultures. Estimates of tourists for 2001, at 700 million travelers, increased to about 900 million in 2008. While citizens of rich countries are obviously overrepresented in such flows, tourism has become infinitely more democratic since the 1970s.

Culture has also become globalized, ranging from secular to sacred. Popular music, movies, and television shows have now become global commodities. This began with the export of easily dubbed American action movies in the 1970s and 1980s, but now features marketing strategies of multiple premieres separated by oceans. References that once would have made no sense to those outside of a particular culture can now be understood by millions of people who don't even speak that culture's language. To a great extent, this process has involved the "Americanization" of global culture, but in the twenty-first century it appears that this will be much more of a polyglot phenomenon than many would suspect. Among the global Indian diaspora, "Bollywood" (the center of Hindi-language filmmaking) is as important as its Californian counterpart. There is a broad geographical representation among the "global celebrities." Consumer products have also become globalized;

where before each country had a national cigarette, beer, soap, and sports team, the last two decades of the twentieth century saw the rise of Marlboro, Heineken, Ivory, and Michael Jordan. Music has also become less of a provincial taste with phenomena from Madonna to the "Three Tenors" on worldwide tours.

Perhaps the most important cultural development of the last quarter of the twentieth century is the ideological hegemony of markets and elections as the operating mechanism for societies. While practiced in myriad ways and never approaching theoretical perfection, capitalism and democracy have become the assumed economic and political options. Other auxiliary political cultural trends include the disappearance of social revolution as an oppositional trope and the rise of nationalist and ethnic appeals. Religion is perhaps our oldest global cultural phenomenon, but no more so than in the twenty-first century. At least in 2010, it is not clear the extent to which a global Islamic movement has moved from organizational conspiracies to a truly social movement, but certainly the Muslim community is much more aware of itself as a global presence than in the past. Similarly the Roman Catholic Church has had to broaden its leadership as its base shifts away from western Europe. The Dalai Lama is recognizable in large parts of the world and pictures of Vishnu can be purchased in almost any city.

Assessing the Pros and Cons

Over the past decade there has been a great deal of discussion of whether the phenomenon of globalization benefits or hurts the majority of the global population. On the pro side, some argue that globalization combines the greatest economies of scale and productive efficiencies to provide everything from consumer goods to medical vaccines to a broader part of humanity. Globalization has also made it more difficult for local despots to hide their crimes or for disasters to remain secret. Explicitly using the model of the market as their base, such arguments defend globalization as providing more for many in unprecedented

ways. Opponents of globalization deny that the balance of benefits justifies the costs of globalization. These include the homogenization of cultures, and the loss of autonomy by smaller regions or ethnic groups. They point, for example, to the eradication of languages over the past few decades as a sign of what is to come. For the opponents of globalization the variety and number of products that it makes available have only led to the creation of a global class divide allowing a small minority of the world's population to emulate the rich. The increase in the relevant market size and the disappearance of national borders have also made it easier for large conglomerates to create effective monopolies. This has led to a "race to the bottom" among societies where each competes to offer the cheapest labor and loosest government regulations.

Part of the argument regarding the overall benefits of globalization concerns the extent to which it is seen as inevitable. For those who judge globalization positively, it seems perfectly obvious that the functional efficiencies of this phenomenon account for its rise. The world was looking for a "better mousetrap," and globalization has allowed us to buy it in several different colors. Attempts to resist globalization can only result in unnecessary suffering, as those left in its wake will not be able to survive. Opponents of globalization do not see it as arising naturally out of the needs of global population, but as a product of the political domination of the United States following the collapse of the Soviet Union, and the preferences of multinational corporations seeking ever greater profits. Producers and sellers want to be able to operate on a global scale and look to the American policeman to protect their interests. A third group that does not necessarily take sides on the benefits associated with globalization sees it as a product of the technological developments of the past decades. Here the ubiquitous computer and that which it makes possible are responsible for creating a global web of connections that forces states, firms, and individuals to perform on a worldwide stage.

If we treat globalization as a process rather than a final state—as a verb rather than a noun—then

much of this debate becomes irrelevant. A historical process can lead to positive or negative results depending on its context or its timing. It may benefit different groups at different times and in different ways. To judge globalization as a final state is particularly dangerous as there has been so little time to appropriately measure and analyze its characteristics and consequences. The process of globalization is also not historically universal, but can proceed in different ways at different times. What defines it is not the end state, but the process of reducing the isolation of territorially defined communities and increasing the interaction and variety of contacts between such communities. It can lead simultaneously to a broader menu of cultural, social, and political choices and to the standardization of models adopted by previously unique groups. If understood as a recurring historical cycle, globalization loses much of its mystery and becomes yet another social phenomenon subject to study and comparison.

There remains considerable debate on the importance of globalization as a social phenomenon (and even about the analytical coherence of such a concept). Not surprisingly, there remains considerable debate on the extent to which the current wave of globalization will continue or be stopped (as were previous ones) by the collapse of the connections and the rise of violent conflicts between regions. Some argue that we are moving toward an ever more globalized world and that nothing can push it back. On the one hand, the dependence on complex technology and advanced engineering do make the current stage susceptible to crashes of one sort or another. On the other, enough of the world's population has enjoyed at least limited benefits from globalization (at least vicariously) to make them strong advocates of the maintenance of some sort of global web of connections.

Gold

Gold is rare, soft, shiny, and highly valued as jewelry. It seldom reacts with other chemicals and can be beaten into very thin sheets to decorate large objects. Its principal use was as coined money after the sixth century BCE. In the nineteenth century gold rushes in California, Australia, South Africa, and Yukon Territory-Alaska created new and diverse communities in a surge of economic activity.

Gold has long been important in trade between regions of the world. As a “precious metal,” gold is uncommon, attractive, easily worked into products, non-reactive, and avidly sought for decorative purposes. Despite being scarce in quantity, gold can be found in many locations around the world, a fact that has made it widely known and admired. The convenience of transporting small amounts of gold, as compared to other trade goods, led the metal to become a universally accepted medium of exchange and standard of value for trade (money).

Gold, along with silver and copper, were the earliest metals used by people. (The working and using of gold and silver are documented back to 4000 BCE. Both metals can be found in a native [pure] state or in other minerals that are processed.) Gold is often washed away from

its original location and deposited in streams and rivers, where it can be easily found. Such sites were the main source of gold until the 1800s. Miners also mined gold veins directly when they were discovered at the surface. Until the 1800s underground miners of gold were often slaves and convicts who worked in miserable and dangerous conditions. Even during the 1800s underground mining of gold and silver remained a difficult and dangerous job. In 2008 the primary sources of gold are mines in China, South Africa, United States, and Australia although gold is mined in some amount in many countries of the world (USGS 2009, 69).

Historically, when a large source of gold was discovered, the discovery often created a “rush” as people desperate to become wealthier tried to find the precious metals.

Gold rushes occurred in California (1848), Australia (1850), South Africa (1850s–1880s), and Yukon Territory-Alaska (1896–1898). These rushes created new communities and brought people from different parts of the world together in a surge of economic activity.

Both gold and silver were originally traded by weight in various forms, but no consistency in purity and size

Solid gold death mask of the Egyptian pharaoh Tutankhamun. The Egyptian Museum, Cairo.

We live by the Golden Rule. Those who have the gold make the rules. • **Buzzie Bavasi (1914–2008)**

Poster circa 1897 for the play *Heart of the Klondike*. Gold rushes brought people from different parts of the world together in a surge of economic activity. Library of Congress.

existed. This lack of consistency led to the standardization of traded gold and silver and eventually to the creation of coins. The first known precious metal coins were made by the nation of Lydia (Turkey) around 600 BCE. Today we still speak of someone “being as rich as Croesus,” who was a king of Lydia (560 BCE). The less-common gold became reserved for royalty and government use, whereas silver became the main trade metal for business.

The search for gold and the control of its sources have had a significant influence on human history as a motivation for exploration, trade, and conflicts. The

story of Jason and the Argonauts (1200 BCE) is about Greeks exploring the Black Sea region for gold. The “golden fleece” of that story was the sheepskin that was used to catch gold in the water troughs used in the early mining process. Gold was sent from Europe to China in exchange for silk and other goods over the Silk Roads through Central Asia (200 BCE to the late 1300s). Gold was brought through Timbuktu (Tombouctou, founded in 1100 CE) in present-day Mali, Africa, on its way north to be traded for salt on the trans-Saharan trade route. The exploration of Mexico, Central America, and South America by Europeans and their frequent conflicts with native peoples were driven by the search for gold.

The commercial role of gold has been changing since the 1900s. Gold has limited use as a medium of exchange for the average consumer, but continues as a store of value held by governments and individuals (especially during financial downturns or times of currency fluctuation). Gold, especially as it is used in jewelry, remains a symbol of wealth and status.

Government

The views and arguments of classical Greek thinkers continue to shape discussions about government, even governments that preexisted the Greeks. Six basic forms predominate: tyranny (rule of one for his own good), oligarchy (rule of a few for their own good), democracy (rule of many for their own good), monarchy (kingship), aristocracy (rule by a few prominent citizens), and good democracy (or “polity,” rule of one, few, or many for the common good).

Serious discussion of the forms of government (or, as we also may call them, regimes or constitutions) that shape cities and countries begins with the classical Greek thinkers. It is in light of their discussion that we first analyze even those governments that preexisted the Greeks. Those early governments were either monarchies or extended villages that did not rise to the level of complexity that the Greeks discovered was necessary for a true city or country.

Greek Discussions of Government

Socrates (c. 470–399 BCE) was the first person to examine human affairs philosophically, and he saw that the core of ordinary human affairs was political. His arguments and views were developed by Plato (c. 428–348 or 347 BCE) in his dialogues. Distinguishing what belongs to the historical Socrates and what to Plato himself is largely a fruitless enterprise, less important than attending to the discussions themselves.

Plato’s purpose in analyzing forms of government was to understand what political life truly is, not what it merely appeared to be under changing

circumstances. The rational search for what truly is the defining element of philosophy and the sciences that later flow from it. The philosophical effort generally begins with Socrates’ predecessors, the so-called pre-Socratics, notably Parmenides (b. c. 515 BCE).

The Greek thinkers argued that politics is the core of human affairs because the polis, the Greek city, is sufficient in its size and complexity to allow the full display of human characteristics in their possible excellence, or virtue. Justice is central among the ethical virtues, and it is the central excellence toward which political organizations and rule aim. Anything smaller or less complex than a city, such as a village, falls short of virtue because it does not allow sufficient leisure or sufficient freedom of discussion among equals about what is better and worse in developing character, conducting war and peace, or pursuing rational arts and skills such as medicine. Smaller units remain too economic in their focus, dealing as they do largely with meeting necessities, and too paternalistic in their rule, being primarily extended families. Anything larger than the city, moreover, such as the Persian Empire that the Greeks fought or the Egyptian Empire that Greek historians such as Herodotus (c. 484–c. 425 BCE) examined, adds nothing vital to possible human excellence, even if it is sufficiently complex and diversified—which many large agrarian territories are not.

The central place of the city means that the Greek discussion of forms of government focuses on it; the fact that the city encompasses the full range of human virtue means that the discussion, if true, is in principle adequate for understanding larger units such as our contemporary countries. The most complete classic discussion of forms of government occurs in

Giovanni Antonio Sasso, *Elevation of the [Roman] Forum at Athens*. Engraving. Built in the first and second centuries CE, the forum is located north of the Acropolis and east of the original classical Greek agora. It served as the market place and administrative center of the city. New York Public Library.

works such as Plato's *Republic* and *Statesman* and, especially, in the *Politics* of Aristotle (384–322 BCE). Aristotle's discussion sets forth the framework in which analyses of constitutions have been conducted from his time forward. Forms of government are divided by how many rule and whether or not the rule is just and serves the common good (rather than the private or class good of the rulers). The six basic forms are tyranny (rule of one for his own good), oligarchy (rule of a few for their own good), democracy (rule of many for their own good), monarchy, aristocracy, and good democracy (or "polity," rule of one, few, or many for the common good).

Aristotle develops this basic classification in a number of ways that make it increasingly subtle and complex. Oligarchy is not merely rule of the few generally but is usually rule of the few who are wealthy, and democracy is rule of the many whose central characteristic is that they are poor. Aristocracy is rule of the few who are ethically virtuous and possess practical wisdom, or "prudence." Varieties of democracy exist that depend on which group from among the relatively poor dominates: farmers, merchants, or the urban poor, for example. Moreover, mixtures exist between the rich and the poor, where the gradations of wealth are so subtle that no group dominates, or where a middle class is superior to either the rich or the poor. Aristotle's view is that such mixed regimes

are the best forms of government one is likely to achieve in practice.

Good government, moreover, is generally characterized by the existence of law (as opposed to arbitrary commands) that citizens accept willingly, rather than government that is imposed involuntarily. The basic laws that distribute functions and offices, moreover, are good when they balance properly the claims to rule that are made by the ethically virtuous and prudent, the wealthy, and the many poor who are free soldiers. All contribute something important to the life or to the good life (the virtuous life) of the community. The good legal and practical balance that we see in mixed regimes or in the better democracies imitates the genuine but rare excellence of rule for the common good of one or a few who are virtuous.

Most governments will be either democracies or oligarchies, with varying degrees of pretension to excellence. Aristotle bases his discussion not only on the intellectual possibilities but on examining the forms of government of many cities, of which only his description of the Athenian constitution fully survives. Together with Plato (and Socrates' contemporary, the historian Thucydides, d. c. 400 BCE), he is especially concerned with the two leading regimes of fifth- and fourth-century BCE Greece, Athens and Sparta, the leading democracy and oligarchy or, some would argue, aristocracy, respectively.

Plato and Aristotle treat the form of government not as a narrow administrative entity but as vital for the overall life of the city: Everything in the city is organized to promote the ruling class's way of life. (We might as easily speak of, say, the democratic way of life as of the democratic regime.) The constitution shows us who rules, and all rulers make law according to a principle of distributive justice, equal to equals and unequal to unequals. This principle normally is made concrete by the unequal wealth or equal freedom in terms of which democrats and oligarchs, respectively, distribute offices and, through law, permit or encourage activities. This is why a significant place among the rulers for the virtuous—those of excellent character and practical judgment—is, for Aristotle, so vital, because to promote and serve the conditions for their excellence is also to serve the community as a whole. One of democracy's advantages is that by

allowing many activities it permits the philosophic or scientific life and, thereby, intellectual excellence. This democratic equality exists at some expense to outstanding moral excellence, however, and in any event, as the trial and death of Socrates makes clear, the Greeks of the time thought that an inevitable tension existed between the unbridled questioning engaged in by thinkers and the beliefs and opinions that cities and countries must take for granted. This difficulty is especially pronounced to the degree that religious belief belongs to or, indeed, forms, a community's laws.

Monarchies before and after the Roman Republic

Aristotle's and Plato's analyses are the basis of subsequent discussion. Factually, monarchies—kingships

Vittore Carpaccio, *The Pilgrims Meet the Pope* (c. 1492). Tempera on canvas. The place of priests and the link between rule and worship was important in Greek cities and in Rome. Gallerie dell'Accademia (Venice).

Let us tenderly and kindly cherish, therefore, the means of knowledge. Let us dare to read, think, speak, and write. • John Adams (1735–1826)

or tyrannies—were the rule in the Aegean and surrounding areas after the conquest of the Greek city-states by Philip of Macedon (382–336 BCE), as they had been in China and Egypt. The most famous such regime was the empire of Alexander of Macedon (356–323 BCE). The outstanding exception was the Roman republic (509–27 BCE). Rome is analyzed and described extensively by residents and observers such as Livy (59 BCE–17 CE) and Polybius (c. 200–c. 118 BCE) and by later thinkers such as Niccolò Machiavelli (1469–1527) and the founders of the United States in the eighteenth century. The Roman Senate made Rome in one sense aristocratic or oligarchic, and growing power for the people added a democratic element. One might even say that short-term dictatorships and consulates involved a monarchical element. Rome was on the whole a mixed regime, emphatically republican (that is, not a monarchy) in its operation and self-understanding until it was replaced by the Roman Empire.

Various kingships and religious empires followed the Roman Empire. The new element was revealed religion, especially Christianity and Islam. The place of priests and the link between rule and worship always was important in Greek cities and in Rome. Aristotle downplayed the question of piety in his political analysis proper, but the connection or even possible identity between obedience to law and to divine commands was clear. Apparently new after Rome was universal and imperial religion and its connection to political life. Christianity in particular gave rise to new questions about the connection between monarchies and the organized priesthood, culminating in the papacy. The leading Christian thinker of the Middle Ages, Thomas Aquinas (1225–1274), did not emphasize these questions, however, but followed as best he could Aristotle's analysis of regimes. We might think of feudal regimes as monarchies that were buttressed by the Church with an admixture of oligarchy. Ties to the land and the link between land and politics, moreover, often made medieval political divisions more hereditary than was common in Greece, with its active democracies, or in the Roman republic,

where the democratic elements supplemented the more hereditary Senate.

Liberal Democracy

Machiavelli's analysis of Rome was one element of the new understanding of forms of government and, especially, of their operation, that triumphed in the West from 1500 onward. It began as a return to Roman and Greek republicanism spurred by concern with the effects of monarchical and priestly dominance, and culminated in the Enlightenment, in the thought of Thomas Hobbes (1588–1679), John Locke (1632–1704), Montesquieu (1689–1755), and others and in the revolutionary governments of England and the United States.

These governments are best called liberal democracies or representative democracies, democracies that seek to protect and employ politically and economically the unequal degrees of wealth, learning, and moral responsibility that their equal freedom and competition often call forth. Such regimes were not fully developed until the founding of the United States, which features the first fully written constitution, and the culmination of Great Britain's Glorious Revolution of the late seventeenth century in Britain's party government of the nineteenth century. Liberal democracies are at the root of much that we consider democratic today. In one guise or another they are dominant in Europe and North America and in many countries in Asia, Latin America, and Africa.

Liberal democracies are variants of the rule of the people; like Greek democracy, they emphasize freedom, self-government, and an orientation toward equality. They differ, however, in several respects. They are based on the equal rights of all individuals rather than, as with the Greeks, on the mere fact of their freedom, defended militarily. As opposed to Greece and Rome, they therefore inevitably press away from slavery, which often was consequent to defeat in battle, even if, as in the United States, they begin by accepting it. They also press toward factual equality in rights for women; women in Greek democracies

enjoyed more liberty, especially within the family, than in many other regimes then and now, but were not equal governors of the city. Liberal democracies, moreover, are based on consent of the governed as a matter of right and choice, not only as a necessity with which governments must deal. They are oriented to economic growth and acquisition, moreover, rather than toward equal distribution of resources or to aristocratic character and the use of leisure and wealth to develop and express this character. They help foster this acquisitive orientation and the intellectual and scientific efforts that aid it through religious toleration, whose effect is to control public religious strife by making religion basically a private affair. They also encourage the forming of countries of great size and diversity because they foster the existence of a variety of competing interests in order to encourage economic growth and to discourage democracy from degenerating to the poor lording or seeking to lord it over the wealthy or the wealthy or any other minority group lording it over the poor.

Because of all this the function of government in representative democracies becomes limited to

regulating private freedom and competition, helping to advance equal rights and opportunity, and providing national security. These limited functions are compatible with extensive efforts and a plethora of laws. Nonetheless, these limits mean that state and society or public and private come to be split much more cleanly than in Greek cities or in the Middle Ages. Types of government no longer shape the whole country or city, but tell us how states are structured to serve society. Indeed, large and complex liberal democratic countries are governed indirectly through representatives rather than ruled directly in assemblies, as was the case with Greek democracies. Representation, however, is less a mechanical device to deal with size than a means to create distance between immediate popular passions and government's decisions. It also permits the special skills, character, sense of responsibility, and enterprise of those who excel to benefit their countries rather than to be at odds with them.

This benefit also is promoted by federal structures and a variety of economic enterprises that enable many to rise to the fore and not compete disastrously

over static resources and positions of leadership. In fact, unlike Greek democracies but with some similarity to the Roman republic as interpreted by Machiavelli and others, modern liberal democracies harness competition to useful ends rather than seeking complete political agreement. By doing this they attempt to increase the longevity of democratic republics; previous democracies were short-lived because for the rich or others whose skills could not be accommodated in a democracy revolution was an attractive choice.

This competition is not only economic or federal, but is internal to governments themselves. Liberal democracies implement and feature political mechanisms such as separation of powers, which checks or limits overweening power should it arise anywhere in government, and political parties, which encourage legitimate opposition to the sitting government.

These principles and institutions were developed by Locke, Montesquieu, Thomas Jefferson (1743–1826), James Madison (1751–1836), Alexander Hamilton (1755–1804), John Jay (1745–1829), and others, primarily in the eighteenth century. Versions of the governments they set in motion became during the twentieth century the dominant governments in Europe, the English-speaking world, and much of Asia. Variants include cabinet or parliamentary systems such as the one in Great Britain, in which the executive and legislative are essentially jointly elected, the U.S. presidential system, which separates the electoral sources of executive and legislative power, and mixed variants in other European states. Some countries even maintain constitutionally limited monarchs. These governments all basically agree in the chief features mentioned above, however, as well as in others such as an independent judiciary, extensive freedom from government interference of speech and press, and an independent civil service.

The domination of liberal democracy did not come easily, nor is it altogether secure. Many French revolutionaries at the end of the eighteenth century supported a smaller, more direct democracy in which civic virtue, not economic enterprise, and more

unitary government, not separation of powers and representation, were the watchwords. Such governments, advocated by Jean Jacques Rousseau (1712–1778), hearkened back in size, although not in subtly developed liberty or sensible expectation, to Aristotle. Rousseau's thought also set the stage intellectually for the attempt to connect government to the nation and to think of states as needing to be nation-states. The kingdoms that made up Germany, for example, were amalgamated by Otto von Bismarck (1815–1898) into a national government, a monarchy that in some respects moved in the direction of constitutional principles. Similar activity occurred in Italy. Such a connection between government and nation was not essential in the original multiethnic representative governments of the United States or United Kingdom, nor in ancient Greek cities, which

The message on this 1920 poster translates into English as “Literacy is the road to communism.” New York Public Library.

were not defined by their dominant ethnic groups or tribes.

Socialism and Communism

The other counter to liberal democracy's spread in Europe was socialism and Communism. Socialism in its benign form is a large degree of state ownership of economic resources that, however, does not seek to change liberal democracy fundamentally. The division between state and society, or the limited purpose of government is, on the whole, still meant to obtain. Such socialism has proved in general to be inefficient economically and to restrict free entrepreneurship. British and Israeli government by their Labor parties after World War II and Swedish government for much of the last half of the twentieth century are examples of its successes and failures. Other forms of socialism, associated with, say, Robert Owen (1771–1858) in the nineteenth century, do seek a more thoroughgoing economic and sometimes noneconomic commonality than the individualism that liberal democracy defends, but such socialist communities never have mastered extensive territories and have lived short lives. Like anarchism and many variations of socialism associated with African and Asian rulers after World War II, they have had minimal effect beyond a single generation in a single place.

The notable exceptions to the very short life of socialist communities are Communism in the Union of Soviet Socialist Republics and its satellites in Eastern Europe, and Communist China. Together with fascism, Communism is the most powerful contemporary version of tyranny and one of the major rivals of liberal democracy. The key analytic question with Communism and fascism is whether they herald or display a new form of tyranny that differs in principles from ancient tyranny, or whether they are at root variants of it. The key practical question is whether liberal democracy has succeeded in overcoming them over the mid or long term.

Many contemporary tyrannies differ little from ancient tyranny except in size and in the modern weaponry and communications that enable them

to be especially murderous. This is true of several twentieth-century regimes in Latin America, Africa, and the Middle East. Communism and fascism, however, seem different enough to have earned the name totalitarian. They differ from ancient tyranny in being based or claiming to be based on principles or ideas (what, under their influence, we call ideologies), in the utter totality of their control of all areas of public, private, and professional life, in the amount of fear and terror they employ, in their level and degree of political and social bureaucracy and organization, in their imperial aggression, in their pretense to great longevity, permanence, and imperial sway, and (sometimes) in their ethnic base.

Their effect, nonetheless, is not different from that of ancient tyranny in the sense that what is bad about tyranny is at root similar in the ancient and modern understanding. The harm does not differ but, rather, is exacerbated by modern totalitarianism's completeness and scope. Ancient tyranny is rule over the unwilling by one (or in an extended sense by a few and even perhaps by many) solely for their private good, that is, solely for satisfying their desires, for exercising their cruelty, or even for giving unbridled reign to their wish to be admired or worshipped. As Plato discusses it, the tyrant seeks to enjoy any pleasure in any manner, even, perhaps especially, the most extreme. As Aristotle explains it, tyranny uses ways and means whose goal is to prevent free men from exercising their own political spirit. It restricts privacy and friendship because it seeks to limit discussion and opposition and to increase fear. It stunts not only freedom, but virtue as well.

The stunting of freedom and virtue and the proclivity to murder opponents and take what is theirs—in a word, extreme injustice—are the hallmarks both of ancient tyranny and modern totalitarianism. Contemporary fascism—Nazism in particular—employed complex political organization and bureaucracy to smother citizens and potential opponents, fully controlled education, communications, and culture, and, as the rulers' willfulness or supposed necessity required, arbitrarily directed the economy, science, and religion. The immediate justification

for these practices was the hardening, development, and dominance of the Aryan race or, more visibly, the destruction of the Jews and the Nazis' other invented enemies. Such arbitrary narrowness, irrationality, and cruelty attempted to justify itself intellectually through Hitler's writings and those of Nazi ideologues.

Communism under Lenin (1870–1924), Stalin (1879–1953), and Mao Zedong (1893–1976) was similar to Nazism in method, goal, and effect. It sought total control of all areas of life, stunted freedom, virtue, and independent political action, aggressively expanded its sway over other countries, and believed or pretended to believe itself justified by the arguments of Karl Marx (1818–1883) about the inevitability and propriety of Communist rule. It differed from fascism in claiming its principles to be universal rather than seeking domination of one particular race. Like Nazism, however, its reality was more in its effects than in its pretenses, in its denying liberty and virtue, and in the tens of millions killed under its regimes. Like fascism it is essentially ancient tyranny writ large with extraordinary scope for its brutality and with large numbers of people complicit with the rulers. The chief new element is the intellectual justification, which, however insincere, adds to the scope and defense of the brutality and impinges directly on freedom of thought by claiming truth in all things. However, even this element of tyranny's intellectual or pseudo-philosophical justification was not unknown to ancient thinkers.

Totalitarianism Defeated?

Totalitarianism fell, among other reasons, because of external opposition in the mid and late twentieth century to the Nazis and Communists. This opposition was organized into alliances and international structures in World War II and the Cold War that brought together but did not eliminate separate, free, governments. The history of international political structures is still another element in the history of forms of government. The founders of the United States, most notably the authors of *The Federalist*,

studied ancient and early modern federations as part of their attempt to devise a federal republic. The philosopher Immanuel Kant and others at the end of the eighteenth century devised plans for and predicted the emergence of federations among liberal republics that would help preserve peace. Such plans became the basis for the League of Nations after World War I and for the United Nations after World War II. Such alliances and structures, and still others such as the European Community, have not developed in the direction of a world state, however, nor has this been widely advocated. A world state necessarily limits free political participation and would seem to be an aid rather than a counter to tyranny should its control fall into the wrong hands.

Totalitarianism also fell because of the essential unnaturalness and therefore instability and distastefulness of its combination of extreme economic, scientific, and bureaucratic organization, complete common ownership, and overwhelming cruelty, arbitrariness, and irrationality. Together and separately these elements are unstable and undesirable. The effect of Nazi and Communist aggression and ideology, however, made their wide or even universal spread possible, especially had they not been countered. Would the unnaturalness of overwhelming brutality, stultifying organization, and completely common ownership have guaranteed their fall, or was the vigorous and armed opposition of free peoples also necessary to prevent their victory?

Contemporary theocracy forces us to raise such questions again; our final topic concerns theocracies or religious regimes generally. Some regimes that are dominated by notions of divine law and do not practice liberal toleration may nonetheless avoid willful or tyrannical demands of their citizens. This can occur if the law respects the free, virtuous, and reasonable as part or indeed the bulk of what is divine in man, and, therefore, if the law permits or encourages actions that stem from these qualities. Such regimes can be monarchies, oligarchies, or even democratic republics as long as the domination of divine law permits extensive differentiation between priests and governors, or between church and state.

An imperial religion that irrationally opposes free thought and inquiry, however, and the virtues of character such as pride and enterprise and the activities that follow from them, is hardly different in its effect from tyranny or totalitarianism. In their opposition to equality of rights and in their wish for total control of thought and action, some contemporary Islamic extremist leaders are quite similar to fascists; indeed, some were taught by or have allied themselves with ethnic particularists. In other cases, the hoped-for totality of control together with extreme violence and doctrines that reject reasonable discussion are similar to the tyrannies of Stalin and Mao. In any event, theocratic tyranny or totalitarianism is at the beginning of the twenty-first century perhaps the chief opponent of liberal democracy.

Greece, Ancient

Ancient Greece, at its peak in the fourth century BCE, fostered Homeric ideals of heroism that inspired writers and philosophers of the classical age to portray the human condition against the world's uncertainties. Greek contributions in science, philosophy, art, literature, religion, and politics thus spread far and wide. European humanists in the fourteenth century revived interest in Greek culture and ideals, which still color contemporary thought.

The civilization of ancient Greece twice effected important changes in world cultural balances, first when Alexander of Macedon (Alexander the Great, 356–323 BCE) conquered a vast empire in western Asia, Egypt, and northwest India, spreading Greek ideas and customs far and wide, and a second time, beginning about 1400 CE, when well-to-do citizens first in Italy and then also in northwestern Europe found that ancient Greek literature provided a useful guide and enrichment for their own lives.

What made Greek patterns of civilization so attractive was that for a few generations a handful of Greek cities mobilized intense and widespread popular participation in politics and war, while also combining monumental public art with market economics. They called this unusual mix “freedom,” and the literary expressions of Greek freedom in poetry, history, and philosophy appealed to intellectually restless citizens in other times and places as both admirable and practical. Freedom continues to figure in contemporary politics, so the Greek example still echoes in our public affairs, though less strongly than it did before 1914, when the study of Greek (and Latin) literature dominated the schooling of Europe’s political leaders

and many of those who supported them. Revival of the Olympic Games in 1896 was a late example of how ancient Greece continued to offer a model for Europeans to emulate, and by now Olympic competition has become worldwide.

The Rise of Ancient Greece

How did ancient Greece achieve its distinctive character? For more than a thousand years after 2000 BCE, when Greek-speaking invaders began to filter in from the north, changes in Greece closely paralleled what was happening elsewhere. The initial invasions, for example, were part of a general expansion of herds-men from the grassy steppes of Eurasia that brought Aryans to India, Persians to Iran, Hittites to Anatolia, and Slavs, Germans, Latins, and Celts to other parts of Europe. The newcomers had the advantage of warlike habits arising from the necessity of protecting their flocks and herds from raiders and from attacking neighbors in retaliation. Moreover, these warrior tribesmen had a superior diet, thanks to the milk and milk products they consumed, making them bigger and stronger than the grain farmers they displaced.

Dry summers prevail in most of Greece and are bad for grass, so the invaders had to depend more on grain farming and to cut back on herding by sending flocks to high mountain pastures in summer. This brought Greek society into line with the contemporary scene in western Asia, where steppe invaders had overrun somewhat larger populations of farmers and the urban centers they supported. Accordingly, by about 1600 BCE, closer encounters with centers of civilization in Crete, Egypt, and western Asia brought familiarity with royal government, bronze weapons

and armor, chariots, writing, and monumental stone construction to Greece. Mycenae became the principal seat of wealth and power, where a massive lion gate and large beehive tombs attest to the greatness of the kings for whom they were built. Rural taxpayers, sometimes conscripted for work on such buildings, together with booty from sea raids along the shores of the Aegean and eastern Mediterranean sustained the kings of Mycenae and rulers of a handful of similar fortress-palaces in other parts of Greece. But chariots as well as bronze weapons and armor were scarce and expensive, so fully equipped warriors remained very few. Hence, about 1200 BCE, when a second wave of Greek-speaking invaders, known as Dorians, armed with comparatively cheap and abundant iron

weapons, advanced from the north, the superior number of their fighting men overwhelmed the old order of society. The newcomers promptly destroyed and abandoned Mycenae and the other palace-fortresses of Greece.

The Homeric Ideal of Individual Heroism

With these invasions, a ruder, more egalitarian age dawned. Writing disappeared, so did monumental building. But bards who recited their poems to the sound of a lyre kept memories of the Mycenaean past at least dimly alive, especially among descendants of pre-Dorian Greek-speakers, known as Ionians. Soon after 700 BCE Homer gave lasting form to this oral

Caryatids, sculpted female figures serving as architectural supports, take the place of a columns or pillars on many ancient Greek buildings.

The unexamined life is not worth living. • **Socrates (469–399 BCE)**

tradition by composing a pair of epic poems. One, the *Iliad*, described a critical episode during a sea raid that Agamemnon, King of Mycenae, perhaps (even probably), led against the city of Troy; its twin, the *Odyssey*, recounted the perilous return of Odysseus from Troy to his home in Ithaca. Homer's poems were soon written down in a new alphabetic script imported (with adjustments) from Phoenicia, and they became fundamental to subsequent Greek assumptions and ideas about how men ought to behave. Homer's heroes seek and attain glory by risking death in war, knowing ahead of time that sooner or later they will be defeated and die. Moreover, according to Homer, the gods play games with men, favoring some, defeating others whimsically; yet the very fact that the gods were immortal meant that they could not be truly heroic by risking life and limb. Instead, according to Homer, they were often merely spiteful and were ultimately subject to Fate—the nature of things—mysteriously spun out in detail by enigmatic, silent supernatural beings. Oddly, therefore, by risking everything, heroic humans surpassed the gods, at least morally, while sharing with them a common subordination to Fate.

This unusual twist diminished the power of priests and conventional religion among the ancient Greeks and opened a path to all sorts of speculation seeking to anatomize Fate and penetrate more deeply into the nature of things, including, ere long, the nature of human society and of morals. No other ancient civilization centered so much on merely human affairs or unleashed human imagination and reasoning from sacred traditions so recklessly. That is why in later times urban populations among whom local versions of sacred doctrine had worn thin from too many encounters with persons of different religious background so often found Greek high culture powerfully attractive.

From Individual to Collective Heroism

Greek civilization further enhanced its attractiveness when Homeric heroism was transformed from an individual, personal pursuit into collective heroism in defense of small city-states, into which Greece

eventually divided. Greek city-states had their own complex development from older migratory and tribal forms of society. Ionian Greeks, fleeing from Dorian invaders across the Aegean to found new settlements on the coast of modern Turkey, led the way. Kinship ties crumbled among haphazard groups of refugees, who consequently had to improvise new ways of keeping peace and order among themselves. Elected magistrates, holding office for a limited time (usually one year) and administering laws agreed upon by an assembly of male citizens, proved maximally effective. When such self-governing communities began to thrive and, after about 750 BCE, started to found similar new cities in Sicily, southern Italy, and around the shores of the northern Aegean and Black Sea, an enlarged Greek world began to emerge, held together by shipping and trade, a more or less common language and the distinctive public institutions of the polis, to use the Greek term for a locally sovereign city-state.

In Greece proper, the polis supplanted older kinship arrangements much more slowly. In the wake of the Dorian invasions, as people settled down to farm the same fields year after year, local hereditary kings, assisted by councils of noble landowners, began to emerge. They much resembled contemporary local rulers of western Asia. Population growth soon provoked a painful process of differentiation between noble landowners and dependent rent- and tax-paying peasants. This process went unchecked in Asia and quickly led to the emergence of new empires and kingdoms, like the biblical kingdom of David. In Greece, however, for something like three hundred years, a different pattern prevailed.

Greek Military and Economic Power

The critical difference hinged on the emergence of phalanx warfare among the Greeks. Beginning about 650 BCE, well-armored farmers, trained to keep in line so each man's shield helped to protect the man next to him, proved superior to disorganized personal combat of the sort Homer had celebrated. When such men, equipped with spears and swords, arrayed

themselves six ranks deep to form what the Greeks called a phalanx, their concerted charge easily swept less disciplined and closely packed opponents before it. Once this simple tactic proved uniformly successful, every Greek city had to maintain and if possible increase the size of its phalanx to be able to protect itself against its neighbors.

Since fighting farmers had to arm themselves for the phalanx with income from the family farm, radical steps were necessary to prevent them from losing their land by going into debt to richer landowners. In Sparta, a (perhaps mythical) lawgiver named Lycurgos (Lycurgus) was credited with setting up a system of military training that required the "equals," as Spartan citizens officially called themselves, to live in barracks between the ages of 20 and 30, practicing military skills and eating together. Family life became correspondingly marginal. Conquered helots in neighboring Messenia supplied the equals with the food they consumed, so Spartan citizens, specialized for war, became an unusual kind of upper class by exploiting the helots collectively. Prolonged military training soon made the Spartan phalanx superior to others, and by 490 BCE Spartans had compelled most other city-states of southern Greece to become their allies.

Athens, the other city whose internal history mattered most in later times, never attained internal

stability to compare with Sparta's under the Lycourgan constitution. In 594 BCE, for example, Solon, after being elected chief magistrate with extraordinary powers, set out to check the decay of the Athenian phalanx by canceling debts and prohibiting debt slavery. But Solon's efforts to invoke justice and "good law" did not make friction between rich and poor disappear. Half a century later a noble usurper, Peisistratus, seized power by force of arms and with popular support, then exiled his rivals so that his sons retained control until 510 BCE. Two years after their forcible overthrow, another nobleman, Cleisthenes, instituted a more democratic regime in Athens. Rivalry between democratic Athens and Sparta's mix of radical equality among a citizen elite and harsh repression of disfranchised helots became overt only after the Persian invasion (490–489 BCE), when a precarious alliance of about twenty Greek cities, led by Sparta, managed to defeat the imperial army of perhaps sixty thousand men that Xerxes I, king of Persia and ruler of the largest empire Asia had yet seen, led against them. This surprising victory proved to the historian Herodotus (d. c. 425 BCE) that free men, obedient to law, fought willingly and therefore better than unfree Persians subjected to a king. More generally, the victory gave an enormous fillip to Greek self-confidence and inaugurated what in retrospect

The Acropolis, with the Parthenon at the top, is perhaps the best-known symbol of ancient Greece.

seemed a golden age of creativity, concentrated especially in Athens.

At the time, however, uncertainty and divided councils prevailed and ceaseless warfare continued to disturb civil society. Those who lived through that tumult would surely be surprised to know how reverently later generations looked up to their accomplishments. For in Athens, self-government by elected magistrates and an assembly in which all citizens could vote provoked perpetual dispute, and war mobilization required ever increasing effort. New thoughts and new dilemmas distracted people in private and public life, while sculpture, architecture, drama, history and philosophy all attained what later generations recognized as classical expression.

This remarkable efflorescence of Greek, and especially of Athenian, civilization was sustained by an expanding market economy. Greek cities began to mint silver, copper, and even iron coins in small denominations, so everyone could buy and sell items of common consumption. Expanding markets, in turn, allowed specialized producers to achieve new levels of efficiency, thus enriching society at large. The most significant of these was specialized farming of olives (for oil) and of grapes (for wine). Beginning not long before 600 BCE, production of wine and oil for sale spread ever more widely through southern and central Greece, wherever climate and soil allowed. That

was because olive oil and wine commanded a ready market throughout the Mediterranean and Black Sea coastlands, where barbarian chieftains mobilized local peoples to supply grain, fish, timber, and other raw materials in exchange for the wine and oil they desired. For a long time terms of trade strongly favored the Greeks, so that the yield from an acre of land under vines or olive trees could be exchanged for far more grain than the same land in Greece could produce. As a result, throughout the classical age commercially specialized farming in Greece sustained free and more or less equal citizens far more comfortably (and in larger numbers) than could have been done by raising their own grain locally. In western Asia cities drew grain from their immediate hinterlands in the form of unrequited rents and taxes, but in Greece ships allowed cities to draw grain and other resources from far greater distances, in return for the oil and wine their farmer-citizens brought to market each year.

Export of specialized artisan products—decorated Greek vases for example—supplemented this fundamental agricultural and raw-materials pattern of exchange. Artisans, too, specialized and rapidly improved the quality and quantity of their output. Thus, for a few generations, increasing wealth and skill concentrated in a few commercial cities, of which Athens was the most active. Eventually, when farmers

in other parts of the Mediterranean learned how to raise olives and vines, Greeks lost their initial advantage. Greek rural prosperity waned correspondingly, and the expansive buoyancy of the classical age, when Greek population and wealth grew steadily, soon faded away. Yet it was political contradictions inherent in polis ideals of heroism and justice that brought an abrupt end to the Greek classical age in 338 BCE, when a semibarbarian conqueror, Philip of Macedon, deprived Greek cities of their cherished freedom. Until then, Greek freedom triumphed on every front, restlessly, ruthlessly, amazingly.

Athens Ascendant

Immediately after their victory over the Persians, Athens and Sparta went their separate ways. Athens had played a conspicuously heroic part in the Persian War. When Xerxes overran their city, Athenians fled to the island of Salamis nearby and refused to surrender. Athenian triremes (the specialized Greek fighting ship that relied on rams, affixed to the ships' prows, to sink enemy ships) then helped to defeat the Persian

fleet in the straits separating Salamis from the Attic mainland (480 BCE), compelling Xerxes to withdraw from Greece with most of his army before the Persian remnant suffered final defeat at Plataea the next year. Thereupon, the Athenians chose to keep their fleet in action and continued the war by sending naval expeditions to liberate Greek cities from Persian rule around the shores of the Aegean and beyond. Peace did not come until 448 BCE, by which time Athens had built an empire, first freeing cities from the Persians and then taxing them to help support the Athenian fleet that "liberated" them. Spartans at first held back, fearful of helot revolt at home and dismayed by the sudden surge of Athenian power.

Within Athens, the fleet's annual campaigns swiftly altered internal balances. Citizens whose surplus younger sons lacked enough land to be able to buy armor and serve in the phalanx now had an attractive way to make ends meet by rowing in the fleet for a small wage, supplemented every so often by hauls of booty. In winter, when the fleet went ashore and stayed home, they were free to attend meetings of the assembly, whereas farmers, scattered across Attica,

Ancient Greek vase painting often depict mythological characters, divine and human.

only attended when an unusual crisis arose. This gave a decisive advantage to property-less citizens and assured continuation of the aggressive overseas ventures upon which they had come to depend for a living. For a couple of generations, farmers served contentedly in the phalanx in summer when there was no work to be done in the fields, while a few wealthy aristocrats went along with the democracy, playing their own specialized part by refraining from conspicuous consumption in private life and competing instead for the honor of using their wealth for various public purposes, like equipping a trireme or financing one of the tragic performances that honored the god Dionysos (Dionysus).

Despite rapid population growth, Athenian citizens remained comparatively few. War losses were substantial, and about a dozen colonies, dispatched to consolidate their emerging empire, also removed several thousand landless citizens. At the city's maximum, in 431 BCE, adult male citizens numbered somewhere between 35,000 and 50,000, of whom as many as 20,000 drew salaries from the state for rowing in the fleet and for other forms of public service, such as serving on juries in the law courts. The total population of Attica was probably between 250,000 and 350,000 persons, almost half of whom were disfranchised foreigners and slaves. So as in Sparta, many though not all Athenian citizens had become militarized "equals," disciplined to row and maneuver their triremes more swiftly and accurately than others, just as years of training allowed Spartan soldiers to prevail on land.

While the Athenian democracy thus concentrated on warfare, trade and artisan work fell mainly into the hands of resident foreigners. Slaves, too, played an important economic role as miners of newly discovered veins of silver ore in Attica. Silver from those mines financed the two hundred Athenian triremes that fought at Salamis; the mines also supplied silver for the Attic drachmae that soon became a standard currency throughout most of the Mediterranean coastlands.

Athens's combination of economic and military power, based on oil and wine exports, other far-

ranging market exchanges, and the personal participation in war by farmer-soldiers in the phalanx and landless rowers in the fleet, was unmatched elsewhere. Athenian polis-wide collaboration always remained somewhat precarious, but under Pericles, who dominated the city's politics between 445 and 429 BCE, the Athenians indeed converted Homeric individual heroism into collective heroism on behalf of their polis. Rich and poor alike pursued honor more than personal gain, and their willing cooperation brought unusual success.

Yet that success was profoundly ambiguous, since victorious Athenians became collective tyrants, suppressing the freedom of others. Accordingly, most Greeks (including some Athenians) came to feel that Athenian democratic and imperial policies were profoundly unjust. Invoking the "freedom of the Greeks" against unjust tyrants, whether home grown or coming from abroad, became and remained a heartfelt protest, long after the enlarged scale of war had made the freedom of separate cities unsustainable.

The Peloponnesian Wars and the Coming of Philip

Sparta, where collective heroism dated back to Lyncourgos, soon took the lead in challenging the emerging Athenian Empire. Two bouts of war ensued. The first, waged on and off between 460 and 445 BCE, turned out to be a draw; but the next Peloponnesian War (431–404 BCE), as the Athenian historian Thucydides called it, ended in the overthrow of Athenian Empire and democracy. Yet the victorious Spartans were compromised from the start, as they prevailed only after accepting Persian money to finance the creation of the mercenary fleet they needed to defeat the Athenians at sea. The scale and intensity of these struggles altered Greek society very rapidly. Fighting became professionalized and commercialized; both Athens and Sparta hired troops and sailors from outside the polis to supplement armies and navies of citizens. Within Athens, rich and poor parted company when conspirators twice (411 and 404 BCE) overthrew the democracy. To be sure, democracy was soon restored in Athens, at

least in form; but the solidarity between rich and poor in pursuit of collective greatness never came back. Instead, independent farmer-citizen-soldiers gave way to mercenaries, while Athens, and Greek society everywhere, divided more and more sharply between landowners and dependent tillers of the soil.

Simultaneously, commercial prosperity subsided as the Greeks lost their primacy in producing oil and wine for overseas markets. Politics changed to match, allowing larger landed property holders to monopolize what long remained vivacious political struggles among themselves at home and with neighboring cities. After 404 BCE, the victorious Spartans quickly became even more unpopular than Athenians had been, before meeting defeat in 371 BCE by the Thebans, who were in turn overthrown by Philip of Macedon in 338 BCE. To keep the peace, Philip made himself commander-in-chief of a Hellenic league of cities. His son, Alexander, after ruthlessly suppressing a revolt, led a combined Macedonian and Greek army against the Persians in 334 BCE. His victories brought the Persian Empire to an end, and after his death in 323 BCE, Macedonian generals set up kingdoms of their own in Egypt, Asia, and Macedon. Greek cities nominally regained their freedom but in fact remained bit players in continuing great power struggles until 31 BCE, when the Romans unified the entire Mediterranean coastline and its hinterlands in a more lasting empire.

Ancient Greek Culture and its Legacy

Long before 31 BCE, Athenian art and literature of the classical age, 480 to 338 BCE, had become familiar to wealthy Greeks everywhere. Precisely because the freedom of the polis was slipping away from their grasp, they cherished the Athenian literary heritage for showing how free men ought to conduct their affairs and lead a good life. Later on, Romans, too, shared a similar nostalgia, for their republican liberty was also a casualty of empire. Accordingly, Roman art and literature borrowed themes and ideas from their Greek predecessors, and the resulting amalgam was what, almost fourteen hundred years later, inspired

Italian and other European humanists to revive ancient glories by teaching the young to read, admire, and emulate Greek and Roman literature and art.

The power and complexity of Greek thought, and its concentration in Athens between 490 and 338 BCE, remains amazing. Reason, imagination, doubt, hope, and fear all play their part in classical Greek literary exploration of the human condition. Fate, gods, and men interact, surprisingly, often inscrutably. Above all, classical Greek writers remained in thrall to Homer, portraying human beings heroically confronting the world's uncertainties. Greek sculptors also portrayed both men and gods in heroic human form, and attained greater visual accuracy than art traditions of Asia or elsewhere had done before. Greek monumental architecture remained simple, featuring columnar façades and straight geometrical rooflines. But subtle curvature and proportion please modern eyes as much as they presumably did when first constructed. In later centuries, classical Greek styles of sculpture and architecture spread widely across Europe and Asia; they still affect many of our public buildings.

Greek Religion

Yet there was more to the Greek cultural heritage than visual art, civic solidarity, and collective heroism. Rational argument, science, and philosophy burgeoned as well, rivaling traditional religious ritual and belief. This aspect of Greek society reflected the fact that religion in Greece had become a hodgepodge by the time written texts allow us to know anything about it. Ancient and secret fertility cults, like the one at Eleusis, promised eternal life to initiates. Such mysteries fitted awkwardly with Homer's quarrelsome gods, living on top of Mount Olympus. In addition, Greeks engaged in ecstatic worship of Dionysos, god of wine, sought cures from Aesclepius (Asclepius) through dreams, and inquired about the future from oracles like that at Delphi, where fumes from the earth intoxicated the Pythia, making her babble in ways that priestly experts interpreted for inquiring visitors. The Greeks also honored the gods

by stripping themselves naked to compete in athletic contests at Olympia and elsewhere at special festivals. This shocked others, but became a distinctive trait of Hellenism as it spread across western Asia in the wake of Alexander's armies, rooting itself in new Greek-style cities founded by discharged veterans.

Greek Philosophy

Nothing resembling a coherent worldview emerged from such confusion, and when Greeks began to buy and sell overseas, they encountered an even greater confusion of religious ideas and practices in Egypt, Asia, and more northerly lands. Polis magistrates could and did reconcile the irreconcilable in ritual fashion by sustaining traditional rites and in some cases elaborating on them, as happened in Athens with the development of dramatic festivals honoring Dionysos. Athenian playwrights, notably Aeschylus, Euripides, and Sophocles, used drama to explore moral and political issues. Although they advocated civic institutions like justice and moral courage as healthy alternatives to the violent uncertainties of human life, they never came near to making the world as a whole make sense. That was left to a handful of philosophers, who, beginning in Ionia with Thales of Miletus (d. c. 546 BCE), took the radical step of disregarding gods and spirits, surmising instead that just as men in the polis regulated their lives by invisible binding laws, nature too perhaps obeyed its own natural laws. Thales for example—perhaps drawing on Mesopotamian creation myths—said that everything came from water by rarification and condensation, with the difference that gods were erased, leaving water and other elements (earth, air, and fire) to behave lawfully. Others pursued this leap in the dark in different directions, proposing some notions that were destined to future significance, like the atomic theory of matter. Mathematics had special attraction for early Greek philosophers since geometrical demonstrations were logically certain and seemed universally true. Here, perhaps, was a model for natural law in general, of which polis law itself was only an instance. Pythagoras of Samos (d. c. 500 BCE) carried

such ideas to an extreme. He founded a secret brotherhood that was soon forcibly dispersed, and taught that the world was made of numbers and that studying their harmonies might permit human souls to survive death through reincarnation. Only fragments remain from the sayings and writings of Pythagoras and other early Greek philosophers, so modern understanding of their efforts to make the world make sense remain very uncertain and imperfect.

Philosophical discussion turned increasingly to human affairs, with the intense controversies surrounding the rise of democracy. Not surprisingly, Athens became the principal center of debate. A school of sophists made their living by preparing young men for political careers, teaching them how to argue a case—any case—convincingly. Some sophists taught that right and wrong were merely human inventions. That in turn provoked others, of whom Socrates (d. 399 BCE) was the most influential, to argue that right and wrong, truth, beauty, honor, justice, and all the other ideas that citizens held dear, were unchanging and rooted in the nature of things, though Socrates was more successful in refuting those who disagreed with him than in explaining his own beliefs. Socrates wrote nothing, but his pupil Plato (d. 347 BCE) pursued the same effort by writing a long series of dialogues that survive for our inspection and continuing delight. Plato wanted to believe in a world of unchanging immaterial ideas that somehow guaranteed truth; but, to judge by his later dialogues, never entirely convinced himself that such a world existed. Nevertheless, Plato's dialogues raised questions for subsequent philosophers to examine endlessly. In addition, by founding the Academy, where young men gathered for advanced study and debate, Plato set up a lasting institutional framework for ancient philosophy. His pupil, Aristotle (384–322 BCE), codified the rules of logic, and his other writings offered plausible answers to almost everything else his predecessors had argued about. Subsequent Greek and Roman philosophers continued to disagree until the Christian Emperor Justinian forcibly disbanded the Academy in 529 CE. All the same, pagan philosophers' ideas provided an educated upper class of citizens in Hellenistic and

Roman times with ready answers to a wide range of personal and scientific questions, independent of any sort of religious authority.

This body of learning—secular, rational, argumentative and complex—rivalled (and also suffused) later religious worldviews. It ranks among the most significant heritages passed on from Greek antiquity, for in later centuries Greek philosophy and natural science took on new life among both Muslims and Christians, and still colors contemporary thought.

In sum, science, philosophy, art, literature, war and politics throughout the world are still influenced by our complex and tangled heritage from ancient Greece.

Green Revolution

The successful development of higher-yielding hybrid strains of corn and wheat (“miracle seeds”) in the early 1960s led to the controversial Green Revolution: big businesses and governments see it as a breakthrough in agriculture and food safety, while small farmers and ecologists see it as ruining the environment, destroying agricultural productivity, obliterating indigenous cultural and agricultural practices, and creating even greater global inequalities.

William Gaud, director of the U.S. Agency for International Development (USAID), coined the term *Green Revolution* in March 1968, and its origins help explain its contested meaning in contemporary history: government development agencies as well as transnational chemical and biotechnology corporations and multilateral organizations such as the World Bank see the Green Revolution (GR) as a miraculous breakthrough in agricultural productivity and food security, whereas small farmers, ecologists, social scientists, indigenous peoples, and community activists see it as ruining the environment, destroying agricultural productivity, obliterating indigenous cultural and agricultural practices, and creating even greater global inequalities through excessive debt burdens for the developing world that further enrich the developed world. How did the Green Revolution give rise to such polarized reactions and assessments? Part of the answer lies in the fact that the Green Revolution, as an application of modern science and technology to agriculture, has never been about just the superiority of one agricultural technology or practice over others—it has been a political, economic, and social event from the start, and so one cannot

be surprised that it has attracted controversy. Part of the answer also lies in how one assesses where and to whom the major benefits of this agricultural revolution went, that is, did they reach the intended recipients?

Definition

The basic elements of the Green Revolution are highly mechanized and energy-intensive production methods (e.g., the use of tractors and mechanical harvesters); a dependence on the intensive use of chemical or synthetic fertilizers, pesticides, and fungicides; a reliance on petroleum-powered machinery and petroleum by-products; the utilization of high-yielding hybrid seeds; uniform planting of one crop species over a large acreage (monoculture); double cropping (two crop seasons per year); large-scale irrigation; and a continuous supply of patented technology and inputs (seeds, fertilizers, pesticides, etc.). The goal was to increase the capacity of plants to use sunlight, water, and soil nutrients more efficiently, and the heart of this revolution in agriculture was the development of certain varieties of patented seeds that fit the requirements of Green Revolution technologies.

Origins

Although its antecedents date to earlier genetic research, the Green Revolution as we know it today began with research conducted in Mexico by U.S. scientists in a wheat and maize research center sponsored by the Rockefeller Foundation during the 1940s and 1950s. Their goal was to develop higher-yielding hybrid strains of corn and wheat.

The remains of the Union Carbide pesticide plant after the 1984 disaster in the city of Bhopal, Madhya Pradesh, India. Photo by Luca Frediani.

The most important person in initiating the Green Revolution in northwestern Mexico was the plant pathologist and geneticist Norman Borlaug. His wheat strains responded well to heavy doses of nitrogen fertilizer and water; the International Center for Wheat and Maize Improvement, established in 1966 by the Rockefeller Foundation in cooperation with the Mexican government, continued his work. With the help of money from the Ford and Rockefeller Foundations, the United Nations Food and Agricultural Organization, and USAID, “miracle seed” spread outside Mexico after 1963 and had its greatest success in an area from Turkey to northern India. The Rockefeller Foundation also sponsored a rice research center, the International Rice Research Institute, in the Philippines in 1960. The institute created high-yield dwarf rice varieties of “miracle rice” that spread to the rice-growing areas of east and southeastern Asia. Researchers at these and private corporate research centers selectively bred high-yielding strains of staple crops, mainly wheat, maize, and rice with sturdy stalks, which were responsive to chemical fertilizers and irrigation water, resistant to pests, and compatible with mechanical harvesting.

Chemical and seed corporations and government officials in developed and developing countries championed the Green Revolution as the solution to problems of famine and malnutrition around

the world. More was involved, however: Excluding Mexico, the U.S.-sponsored enterprise encircled the Communist world from Turkey to Korea. Although fears of the spread of Communism motivated U.S. politicians and businesspeople, the idea of scientifically designed crops to improve living standards was also promoted within socialist societies from the Soviet Union to China to Cuba. In many ways the Green Revolution started as an economic wing of Cold War politics.

Positive Results

The incubation of the Green Revolution occurred during the 1950s and 1960s, and it dramatically altered food production during the 1970s and 1980s. In 1970 around 15 percent of the Third World’s wheat- and rice-growing areas were cultivated with the new hybrid seeds. By 1983 the figure was more than 50 percent, and by 1991 it was 75 percent. Proponents argue that more than half of all economic benefits generated by GR technologies have gone to farmers and that plentiful harvests became commonplace in much of the world during the thirty-five years after 1960: Crop yields of wheat nearly tripled, those of rice nearly doubled, and those of corn more than doubled in ninety-three countries. Because of high-yield rice and wheat, scores of countries kept food production ahead of population growth.

The Green Revolution promised agricultural plenty and prosperity. Photo by Joan Lebold Cohen.

Learning from the mistakes of its first applications, newer GR technologies promised increased net returns and reduced chemical loads for farmers. The Green Revolution was most successful in India in increasing aggregate food production: During 1978 and 1979 India established a record grain output of 118 million metric tons and increased its grain yield per unit of farmland by 30 percent since 1947. India has not had a famine since 1965–1966. However, no other country that attempted the Green Revolution matched India's success or the number of jobs in auxiliary facilities such as chemical factories and hydroelectric power stations.

Proponents such as Martina McGloughlin point out that GR technologies create more food for sale, increase foreign exchange and national income, and generate a steady income source for successful growers as well as new nonagricultural jobs. Proponents do not believe that the adoption of biotechnology crops is creating genetic uniformity or inducing vulnerability to new strains of pathogens. They assert that GR technologies are size neutral and can promote sustainable agriculture centered on small farmers in developing countries. Despite such claims, the Green Revolution has promoted monoculture worldwide because each hybrid seed crop has specific fertilizer and pesticide requirements for maximum growth: Farmers save money by buying seed, fertilizer, and pesticide in bulk and by planting and tending the same crop uniformly on their land.

Negative Outcomes

The picture is not all rosy, however. Despite claims by proponents, monoculture did make crops more susceptible to infestations and damage by a single pest. When farmers turned to heavier doses of petroleum-based pesticides, the more-resistant pests survived, and their offspring returned the next year to cause even greater losses. Famous cases of such resistance are the southern corn leaf blight in 1970 and 1971 in the United States; the brown planthopper, which attacked the various strains of “miracle rice” during the 1970s and 1980s in the Philippines, Sri Lanka, Solomon Islands, Thailand, India, Indonesia, and Malaysia and in Thailand, Malaysia, and Bangladesh again in 1990; and the recent potato blight in the Andes. Millions of people, mostly agricultural workers, suffer from acute pesticide poisoning, and tens of thousands die every year from it. The horrific explosion at Union Carbide's Bhopal, India, plant on 2 December 1984 killed an estimated 3,000 people and injured 200,000 more. The chemical Sevin manufactured at Bhopal was essential for India's Green Revolution. In addition, ever-rising doses of pesticides have meant that they ended up in water supplies, animal and human tissues, and soil with often unforeseen consequences. Along the Costa Rican coast 90 percent of the coral reefs are dead due to pesticide run off from plantations that monocrop bananas for export and that have ruined 80,000 hectares of former banana plantation

land with copper residues from pesticides so that the land can no longer be used to grow food for either domestic consumption or export. Costa Rica now imports basic staple grains: beans, corn, and rice.

The irrigation required by the Green Revolution has led to massive dam-building projects in China, India, Mexico and elsewhere, displaced tens of thousands of indigenous peoples, and submerged their farmland. The frequent result of massive irrigation has been the creation of soil with a high salt content that even large doses of fertilizer cannot repair. Critics have documented the reduction in species diversity that followed the Green Revolution. Rice, wheat, and maize have come to dominate global agriculture: They supply 66 percent of the world's entire seed crop. They have edged out leafy vegetables and other food crops that do not respond to nitrogen- and water-rich farming regimes. Critics note that human beings cultivated more than three thousand plant species as food sources before the Green Revolution, whereas today fifteen species (among them rice, corn, wheat, potato, cassava, the common bean, soybean, peanut, coconut, and banana) provide more than 85 percent of all human nutrition.

The energy requirements for this agriculture are high: In what Southern Illinois University professor of anthropology Ernest Schusky has dubbed the "neo-caloric revolution" GR agriculture is one-half as energy efficient as ox-and-plow agriculture and one-quarter as energy efficient as hoe agriculture. The model of GR agriculture, U.S. grain farming, is remarkably energy inefficient: It consumes eight calories of energy for every one calorie it produces. For critics thirty years of the Green Revolution have left a legacy of environmental degradation, unsustainable agricultural practices, social disruption, homeless farmers, ruined farmland, crushing international debt burdens for developing countries, and the export of needed food to meet loan payments.

A Mixed Legacy

Opponents and proponents alike admit that the benefits of the Green Revolution are unevenly spread.

Wealthier farmers with dependable access to water and credit prospered, whereas those farmers who skimmed on fertilizer and irrigation because of the extra costs did not do well, and their yields were no greater than before. Agrochemical industries, banks, large petrochemical companies, manufacturers of agricultural machinery, dam builders and large landowners have been major beneficiaries. The social results in the United States and elsewhere have been a reduction in the number of small family farms, the concentration of agricultural wealth in fewer hands, growing social inequality, and migration to cities. In the case of Taiwan, South Korea, and Indonesia, producing more food with fewer people and the exodus of people to cities helped fuel industrialization. In other countries it merely increased the urban slum-dwelling poor. Internationally, South Korea, China, India, and Mexico reduced or eliminated food dependence, and India became a net food exporter. Other nations did not fare so well: Until 1981 the developing world was a net exporter of food; after 1981 it was a net importer.

Although India is the Green Revolution success story, its Punjab region has experienced all of the revolution's negative ecological and social consequences, and Indian children are suffering from a vitamin A deficiency that is causing blindness in forty thousand children a year. Enthusiasts of the new "Gene Revolution" report that scientists are genetically altering rice so that it contains beta-carotene, which enzymes in the intestine convert to vitamin A when needed. Critics argue that vitamin A deficiency is best seen as a symptom of broader dietary deficiencies caused by a change from diverse cropping systems to rice monoculture: Indian children have vitamin A deficiency because their diet has been reduced to rice and little else. Under a mixed agricultural regime, Indian farmers grew *brathua*, a traditional plant rich in vitamin A, along with their wheat, but in GR monocultures *brathua* is regarded as a pest and is destroyed with herbicides.

In reaction to the myriad problems caused by the Green Revolution, an alternative agriculture called "LISA" (low-input sustainable agriculture) emerged

in the United States, Cuba, western Europe, and elsewhere in the late 1980s (in 1990, in the United States, it was renamed Sustainable Agriculture Research and Education Program [SARE]). It sought to promote ecological sustainability in farm production by replacing dependence on heavy farm machinery and chemical inputs with animal traction, crop and pasture rotations, soil conservation, organic soil amendments, biological pest control, and microbial biofertilizers and biopesticides that are not toxic to humans. A carefully watched experiment with LISA occurred in Cuba, where the end of Soviet pesticide and petroleum subsidies in 1991 led to the collapse of GR-based food production and near famine from 1991 to 1995. In 1993 the Cuban government began breaking up large state farms, changed land tenure toward cooperatives, and replaced the Soviet Green Revolution model with the LISA model on a national scale. Food production rose slowly from its low in 1995 to approach its old levels by 2005, and continues to rise. A contributing factor is the cooperative system (as of the 2008, the state owns about 65 percent of all tilled land; the cooperatives comprise 35 percent but produce 60 percent of all Cuba's agricultural crops).

Implications and Directions

The Green Revolution has fervent admirers and detractors. Admirers who wish to mitigate its worst effects are promoting the Gene Revolution, which combines specific genes (and their desirable traits) among unrelated species to yield plants with novel traits that cannot be produced by farmers practicing traditional breeding. The result is the engineering of "transgenic" crops such as rice with beta-carotene or plants that produce pesticides to protect themselves or vaccines against malaria and cholera. Those people who promote LISA endorse agroecology, which entails grassroots efforts by small farmers and scientists to meld traditional and modern farming methods, to reduce pesticide and chemical fertilizer use, to select natural seed varieties suited to different soils and climates, to end monoculture and export orientation,

and to use science to enhance natural ecological systems of agricultural production and protection. The choices that people make in the first decades of the twenty-first century will shape not only the kinds and amounts of foods that people will have available to eat but also the ecological health of the planet itself.

Born circa 1020 and baptized as Hildebrand, Pope Gregory VII served six popes before he himself was elected in 1073. His main theological concerns focused on the superiority of church over state and a pope's right to be the final arbiter of all significant church disputes. He was beatified in 1584 and canonized as Pope Saint Gregory VII in 1728.

Pope Gregory VII, whose baptized name was Hildebrand, is considered to be one of the most influential popes in the history of the Roman Catholic Church and in European history.

Although his early life remains a mystery, his origins were quite humble. At a very young age, Hildebrand was sent to be educated at a Cluniac monastery in Rome. As a Benedictine monk, he entered the service of the future pope Gregory VI and later served as his chaplain. Prior to his own selection as pope, Hildebrand served six different pontiffs, rising in power and prestige during this time. His remarkable talents as administrator would later define his role as head of the Roman Catholic Church. Two central themes dominate Hildebrand's theological mind-set: the superiority of church to state, and all significant church matters of dispute were to be resolved by the papacy. In light of these positions, his papacy was dominated by conflict from both within and without the church.

After the death of Pope Alexander II (1073), Hildebrand was acclaimed the new pontiff. Consecrated in 1073 as Gregory VII, Hildebrand honored the memory and legacy of his earliest patron, Gregory VI. Gregory VII took the helm of the Catholic Church at a time when it was undergoing one of its most

devastating periods of moral decay. His resolve of moral character allowed him to attempt reforms within the church and battle its most significant problems: the buying and selling of sacred offices (simony), clerical incontinency, and lay investiture. Another issue of concern for the reforming pontiff was an effort to free the eastern Christians from the Seljuk Turks.

Federico Zuccari, *Pope Gregory VII absolving Emperor Henry IV*. The emperor supposedly stood barefoot in the snow for three days, begging the pope's forgiveness.

In response to a letter (1073) to the pope from the Byzantine emperor Michael VII (reigned 1068–1078), Gregory VII wrote to the European monarchs and princes urging them to rally support for the defense of the Christian East. This call, however, met with indifference and opposition.

In his efforts to reform the church and restore its integrity, the pontiff deposed (1074) a number of bishops who had bought their offices. That same year he issued a papal encyclical that absolved people from their obedience to local bishops who allowed their clergy to marry. In 1075 he ordered the abolishment of lay investitures. Finally, he affirmed Gregory VI's spiritual sovereignty over monarchs. In his efforts to reform the church, Gregory VII was met with a storm of opposition. He was opposed not only by laymen but by the clergy, especially by the bishops. Eventually, Gregory VII waged a fierce battle against his chief rival, Holy Roman Emperor Henry IV (1050–1106).

The conflict between the pope and emperor, known as the Investiture Controversy (1075–1122), was primarily a dispute over whether the imperial or the papal power was to be supreme in Christian Europe. The current phase of the controversy culminated in both Henry IV and Gregory VII excommunicating each other. During Gregory VII's trip to Augsburg to depose Henry IV and select a new emperor, he was met at the Castle of Canossa by Henry IV, who supposedly stood barefoot in the snow for three days begging the pope's forgiveness. Although the matter was resolved temporarily, subsequent disputes between the two leaders would lead Henry IV

to march on Rome and force the pope to flee and take refuge.

Pope Gregory VII died at Salerno on 25 May 1085. Prior to death, Gregory VII absolved all whom he had excommunicated with the exception of Henry IV and the antipope Guibert. According to religious history accounts, the pontiff's final words were "I have loved justice and hated iniquity; therefore I die in exile." His body was interred in the Church of Saint Matthew in Salerno. Hildebrand was beatified in 1584, and canonized as Pope Saint Gregory VII by Pope Benedict XIII in 1728.

Guevara, Che

(1928–1967)

LATIN AMERICAN REVOLUTIONARY

The Argentine-born revolutionary Ernesto “Che” Guevara is renowned worldwide for his commitment to international social justice during the mid-twentieth century. Although he was both hated and loved for the guerilla warfare tactics he advocated in Cuba, the Congo, and Bolivia, his writings continue to offer insight into world history from the perspective of an internationalist, rather than one committed to a nation-state.

Ernesto “Che” Guevara’s image is known worldwide, appropriated globally by people identifying with his sense of social justice, idealism, and rebellion. An Argentine who fought for independence in Cuba, the Congo, and Bolivia, Guevara represents a stateless “new man” committed to international socialism. His published critiques of capitalism and imperialism reflected an understanding that both the problems and solutions of the twentieth century were global in scope.

Born in Rosario, Argentina in 1928, Guevara was homeschooled until he was nine years old due to severe asthma. All his life Guevara read voraciously and by adulthood was knowledgeable on subjects that included literature, Latin American and Spanish poetry, French existentialist philosophy, Marxism-Leninism, psychology, and archaeology. In December 1952, Guevara took an eight-month break from medical school to travel to South America with a friend. He witnessed the general condition of indigenous peoples throughout South America and was particularly moved by the working conditions of copper miners in Chile. He attributed Latin America’s

economic problems to heavy penetration by foreign corporations.

After graduating in 1953, Guevara continued traveling, winding up in Guatemala City where President Jacobo Arbenz was challenging the U.S.-owned United Fruit Company’s claim to Guatemala’s fertile land. Here Guevara met Hilda Gadea, a Peruvian activist who introduced Guevara to the ideas of Mao Zedong. Together they watched the 1954 CIA-sponsored coup overthrow Arbenz, plunging Guatemala into more than four decades of political violence. The coup solidified Guevara’s belief that Latin America’s major problem in the 1950s was “Yankee imperialism,” which he understood as the combined political, military, and economic power that U.S. policy makers and corporations and their local collaborators held over the region’s economy. It also persuaded him that armed revolution would be required to fix the problem in most of Latin America.

Guevara and Gadea parted ways, seeking the protection of their respective national embassies; by coincidence, they reunited in Mexico City and married. It was here that Guevara met Fidel Castro (b. 1926), who had led a failed effort in Cuba to overthrow the dictatorship of Fulgencio Batista in 1953. After serving less than two years in prison, Castro and other Cuban exiles were regrouping in Mexico City. Castro and Guevara connected immediately. The Cubans shared Guevara’s concern for the power wielded over Latin America by the United States and planned to do something about it. On 25 November 1956 eighty-one Cubans and Guevara launched their invasion of Cuba.

Silence is argument carried out by other means. • **Che Guevara (1928–1967)**

Che Guevara, shown in a detail from the iconic photograph *Guerrillero Heroico*, taken on 5 March 1960, when Che was thirty-one years old. Photo by Alberto Korda.

Originally the group's doctor, Guevara proved an excellent guerrilla fighter, earning the highest rank among the rebels, and it was his column's January 1958 entry into Havana that marks the victory of the Cuban revolutionary forces. During the war, Guevara established a school for teaching guerrilla fighters to read, a printing press, and a radio station. He also met Aleida March, who became his second wife. He later published the first official history of the Cuban Revolution and popularized the *foco* theory of guerrilla war, which argued that small groups of committed individuals could create the conditions for revolution on a wider scale.

After the war, Guevara served as minister of industry and head of the national bank. But Guevara's numerous publications, speeches, and worldwide role as the Cuban Revolution's public face were what made

him a celebrity both hated and loved. The prototype for the "new man," Guevara was motivated by moral incentives and hoped to eventually eliminate money. Encouraging international cooperation to establish socialist societies, Guevara represented a humanist Marxism, offering new possibilities for communists opposed to Stalinism.

Although a diligent bureaucrat, the position did not suit him. In 1965, Guevara "disappeared" from Cuba, quietly organizing a disastrous guerrilla war for independence in the Congo. Despite renouncing his Cuban citizenship in a farewell letter to Castro, Guevara returned to Cuba in March 1966. Determined to remain no longer than necessary, Guevara launched his final guerrilla campaign that fall, hoping to inspire a peasant revolution in Bolivia. His guerrillas fought their last battle on 8 October 1967 against Bolivian army rangers working with the CIA. Guevara was captured and executed the next day.

Controversy surrounds Guevara's legacy and revolutionary methods, but his analysis of imperialism as a way of understanding the past and present offers insight into world history from the perspective of an internationalist, rather than one committed to a nation-state. His ideas and martyrdom continue to inspire social justice movements. While Guevara's place in world history as a global revolutionary is secure, his contribution as a social and political thinker continues to unfold.

Guilds

Artisans, merchants, and other workers formed guild associations throughout history as a way to standardize practices in their professions. As their legal powers grew, guilds regulated production, fixed rules for apprenticeship, restrained competition, and countered foreign competition with precise ordinances. By the beginning of the nineteenth century, with growing economic deregulation, guilds were considered an obstacle to progress and were abolished worldwide.

Guilds, in both the Middle Ages and the modern age, may be understood as those associations, particularly typical of western Europe, formed by artisans, merchants, and other workers who perform the same job and have to submit to certain rules. They have been known as *corporazioni* or *arti* in Italy, *zunfte*, *gilden*, or *handwerke* in Germany, *métiers* or *corps* in France, *gremios* in Spain, and *gilde* in those countries overlooking the Baltic Sea.

Their origins are old. In the ancient Greek cities there were associations with religious and charitable purposes. They arose in Egypt, too, and in ancient Rome from the third century BCE as free associations (*collegia*, *corpora*, or *artes*) controlled by the state. Following the decline of the Roman Empire, the barbarian invasions, and the decline of cities, these associations disappeared, then revived after the year 1000 all over western Europe, although the link between these associations and the previous ones is not very well established. In contrast, the derivation of the Byzantine guilds from the Roman ones has been proved. In Japan, by comparison, guilds arose much later than in other countries: it was only between the seventeenth and eighteenth

centuries that town merchants (or *chonin*) united in privileged associations, in order to oppose the feudal landowner. As regards Arabian towns, we do not know anything about artisan or commercial guilds before the fifteenth century. In India guilds developed under the Mughal Empire, in the seventeenth century, bringing together mostly traders, but they were controlled by the state; in Constantinople the government used to name the guilds' heads directly, as guilds had the function of supplying the city with food. The same thing happened in the Ottoman Empire, while in China guilds were weak or did not exist at all, due to the predominance of foreign merchants. In England the existence of guilds can first be proved in 1087.

Guilds in Europe could be professional communities that were very narrow (rope makers, wool carders) or quite wide (cloth makers). A famous skilled guild arose in Spain: the *mesta*, which united the sheep breeders, was established in 1273 by Alphonso X of Castile. Sometimes guilds were connected with ethnic minorities. For example, in Tudela, Spain, in the late thirteenth century, Moors had a monopoly on iron and leather working. This was the only such case in Spain, however, and it did not recur elsewhere because in nearly the whole of Europe, ethnic minorities were often excluded from guilds. Even more complete was the formal exclusion of the Jews, who were usually prevented from organizing their own guilds, at least until the seventeenth century, with the exception of concessions and derogations. Thus a turning point was marked with the 1648 royal decree by Habsburg monarch Ferdinand III of Hungary, who allowed the Jews of Prague to carry on with all kinds of jobs.

Thomas de Keyser, *The Syndics of the Amsterdam Guild of Goldsmiths* (1627). Oil on canvas. Toledo Museum of Art (Toledo, Ohio).

As their legal powers grew, guilds regulated production, fixed rules for apprenticeship, restrained competition, and opposed foreign competition with precise ordinances. Internally, they designated their officials, and their membership was subdivided into masters and apprentices (*maestri* and *garzoni* in Italian; *maîtres apprendistes* and *garçons* in French; and *meister* [master], *geselle* [journeyman], and *schelinger* [apprentice] in German). Each guild formed a special jurisdiction: the heads of the guild judged controversies between its members and technical disputes about the trade. From the twelfth century onward, guilds appeared in towns as separate entities with their own legal status.

In many countries, as time went by, there developed a politically significant distinction between major and minor guilds: The former were usually constituted of merchants (e.g., the *six corps marchands* in Paris; the *herrenzunft* in Basel; and the *arti maggiori* in Florence, where they seized power in 1293), while the latter were mostly constituted

by artisans. As regards the guilds' organization, it is necessary to distinguish between those areas—Venice, Sicily, France, Aragon, and Catalonia, some parts of the German Empire, the Mughal Empire in India—where the central power was able to keep its own privileges and those where it had to share these privileges with class interests. Thus in large independent cities, such as Milan, Florence, Siena, Bologna, those of Flanders, and some German cities, guilds played a political role in government. Nevertheless with the creation of great nations, guilds lost their power and became more and more closed, monopolistic circles.

With the appearance of the eighteenth-century doctrines of the Enlightenment and English liberalism, and with growing economic deregulation, guilds were seen as an obstacle to progress. The guild system was abolished for the first time in Europe in 1770 by Leopold II of Tuscany, then in 1791 by the French National Assembly and, finally, during the Napoleonic era, at the end of the eighteenth and the beginning

of the nineteenth centuries, almost all over Europe and the world.

Gum Arabic

Ancient Egyptians used gum arabic, a sap-like product from acacia trees grown near the Saharan and Arabian deserts, in mummification; successive societies valued it as a drink thickener, a wall glaze, and a hairdressing product. Its use in manufacturing silk and cotton cloth caused a boom in its trade in the early 1800s. Today gum arabic can be found in cosmetics, confections, and beverages.

Gum arabic is one of the oldest and the most versatile of the Afro-Eurasian regional trade goods. A tasteless, viscous, light-colored, sap-like product of several varieties of acacia trees that grow along the edges of the Saharan and Arabian deserts, gum arabic exudes naturally when the acacia bark splits under the force of desiccating desert winds. Harvesters can also artificially induce the exudation by making knife cuts in the bark.

In ancient Egypt artisans used gum arabic in making inks and in the process of mummification. In the desert societies of the Sahara and Arabia, it was used as a foodstuff, a thickener for drinks and glue, a glaze for mud-walled construction, a cosmetic hair treatment, a base for painting on wood, and a medicine for diarrhea. It found many additional uses in neighboring societies, including in papermaking and in cloth finishing.

Until the middle of the second millennium CE, gum arabic reached Mediterranean and southwest Asian markets principally from Arabia and northern Africa. After the fifteenth-century maritime revolution, European mariners discovered an abundant source of gum arabic along the southern coast of the western Sahara. Gum arabic exports from this region, however,

remained modest until the eighteenth century, when manufacturers extended techniques for the use of gum arabic in the production of silk cloth to the manufacture of cotton cloth. Thereafter, the importance of gum arabic increased, and the “gum coast” became an arena of international contestation.

The principal markets for the seasonal purchase of gum arabic were located along the Saharan coast of Mauritania and at river ports along the lower Senegal River. The Arabo-Berber tribes who controlled the gum harvest sent their slaves to do the arduous work of scrapping the gum into leather sacks that later would be loaded on to draft oxen and carried to market. European merchants along the Saharan coast bought the gum from desert caravanners and took it on board their ships. Afro-European merchants bought the larger volume of gum arabic at the river markets from desert merchants and bulked it in warehouses in Saint-Louis du Sénégal at the mouth of the Senegal River before it was transferred to ocean-going ships.

During the Seven Years’ War (1756–1763), Thomas Cumming, a U.S.-born gum arabic trader based in London, led a small expedition of British naval vessels in a successful attack upon the French colony of Saint-Louis du Sénégal. The British seizure of Saint-Louis in 1758 marked the beginning of the first of two periods of British colonial rule in northern Senegambia (1758–1779). The British also briefly gained control of Saint-Louis during the Napoleonic Wars.

During the 1820s and 1830s the volume of gum arabic exports doubled. The gum arabic trade became the overwhelming focus of European, Euro-African, and Arabo-Berber merchants and the Arabo-Berber warrior groups along the southern shore of the Sahara

who participated in the Atlantic sector. Terms of trade moved heavily in favor of the Arabo-Berbers, and large volumes of the principal import, an indigo-impregnated cloth known as the “guinée,” flooded into the region. The desert merchants, adept at exploiting their market position, created intensely competitive conditions among the European and Euro-African gum arabic traders at Saint-Louis who sought their trade. The desert warriors exploited their ability to extort tax payments from the gum arabic traders. During the 1830s and 1840s many of these Euro-African traders fell into ruinous debt. This crisis in the gum arabic trade provoked the French conquest of the lower Senegal River valley during the early 1850s; it was in part an effort to break the power of desert warrior groups and to reorganize the gum arabic trade. This conquest was the first inland territorial conquest by the French in sub-Saharan Africa.

Thereafter, import-export commercial firms at Saint-Louis imposed their control over trade in gum arabic, and gum arabic remained the principal export from the Senegal River valley throughout the remainder of the nineteenth century. The value of gum arabic declined sharply, however, as new industrial products and processes reduced the importance of the natural exudate. New sources were developed in the Sudan, and these managed groves of acacia emerged during the twentieth century as the principal source of the world's supply of gum arabic.

Thus, beginning in the mid-nineteenth century, gum arabic returned to its earlier role as a natural product with only an exceedingly modest importance in world trade. Today gum arabic continues to find a wide variety of uses in lithography and in the production of cosmetics, confections, and beverages.

The Babylonian king Hammurabi (reigned 1792–1750 BCE), a skilled military commander and a clever politician, is best known for the large stele on which he had some 282 laws inscribed. This so-called Code of Hammurabi, the longest text extant from Babylon's first dynasty, includes an epilogue of curses on anyone who destroyed the stele and blessings on anyone who refurbished it properly.

Hammurabi (or Hammurapi), who reigned from 1792 to 1750 BCE (according to the most widely accepted chronology of ancient Mesopotamia), was the sixth and most prominent king of the first dynasty of Babylon (1894–1595 BCE). Ethnically, the rulers of the first dynasty were a family of Amorites, a mostly rural group, some of whom nevertheless became rulers of city-states in Babylonia and Syria just after the beginning of the second millennium BCE. When the earliest member of the first dynasty, Hammurabi's ancestor Sumuabum, began to rule (1894 BCE), Babylon was a relatively small and unimportant town. By the time of Hammurabi's father, Sin-muballit (reigned 1812–1793 BCE), Babylon had grown somewhat in size, and its authority extended to several nearby towns, so that Hammurabi inherited a fair-sized state, estimated to have been roughly 10,000 square kilometers.

Hammurabi proved to be both a skilled military commander and a clever and patient politician. He joined coalitions with rulers of similarly sized city-states to defeat common enemies, and, when the opportunity presented itself, changed allegiances or attacked former allies to enlarge his own territory. When he defeated the long-reigning king Rim-Sin (reigned 1822–1763 BCE) of the powerful city of Larsa, capital of the state of Emutbal to the south, he added most of southern Mesopotamia to his realm in one stroke. Two years later, in his thirty-second year on the throne, he conquered a former ally, the city of Mari some 400 kilometers up the Euphrates River, making Babylon the preeminent power in Mesopotamia, vying in extent and might only with the Syrian kingdom of Yamhad and its capital Aleppo. Little archaeological or textual material remains from Babylon itself during this period, because the rising water table has made excavation difficult.

There is, however, an abundance of evidence from nearby cities that were under Babylon's hegemony, so that we are well informed about the social structure, economy, and political intrigue of the period. The textual evidence includes many royal (dedicatory) inscriptions and vast numbers of legal documents and letters. Many of the letters are from Hammurabi himself (undoubtedly dictated

Detail of the famous stele containing Hammurabi's law code. Louvre, Paris.

If any one buy the cattle or sheep which the king has given to chieftains from him, he loses his money. • **Hammurabi, Law 35 (eighteenth century BCE)**

A portrait of Hammurabi carved as a relief sculpture, circa 2200 BCE. British Museum.

to a scribe), addressed to his viziers in the major cities, commanding them, for example, to restore to a farmer a field illicitly taken from him, or to dredge the local canal, or to collect certain taxes; he clearly involved himself in the smallest details of administering his large realm. Much of our knowledge of Hammurabi's military expansion derives from how the years of his reign were designated—in this period in southern Mesopotamia, years were designated by a significant royal event or activity, such as “(the year) he defeated Emutbal and its ruler Rim-Sin.”

In addition to his involvement in the kingdom's day-to-day administration, Hammurabi carried out other traditional duties of a Babylonian ruler, such as building or rebuilding temples in many of the cities under his control, fortifying city walls, and serving as the prime dispenser of justice. Hammurabi seemed particularly keen to portray himself as a “King of Justice” (the name he gave to a statue of himself, after which his twenty-second year was named). And, indeed, Hammurabi is best known for the large stele of

polished black diorite on which, near the end of his reign, he had some 282 laws inscribed. The “Code of Hammurabi,” as it is commonly, though imprecisely, called, is the longest text extant from the first dynasty. The text includes not only the laws, but also a prologue, in which the gods call upon Hammurabi “to proclaim justice in the land, to destroy the wicked and the evil, that the strong may not oppress the weak” (author's translation) and a lengthy epilogue of curses on anyone who destroyed the stele and blessings on anyone who refurbished it properly.

The laws do not constitute a code in the strict sense (i.e., a comprehensive and systematically arranged set of laws), but are rather a collection of individual cases. An example is No. 193: “If a son has struck his father, his hand will be cut off.” Among the topics covered in the laws are trials, theft and kidnapping, land tenure, commerce (regulation of merchants, financial transactions, debt), the family (women, marriage, inheritance, adoption), assault, professional fees and rates of hire, and slave holding. Although it is not the earliest such collection of laws in Mesopotamia, it is by far the most comprehensive. The interesting fact has been noted by scholars that Hammurabi's “Code” is almost never referred to in the many legal texts attested from the period. Hammurabi and his code, however, remain of historic import because of the massive nature of the code—both as a physical monument and as the first such extensive collection of laws discovered.

Han Wudi

(156–87 BCE)

CHINESE EMPEROR OF THE HAN DYNASTY

The Chinese emperor Han Wudi remained in power from 140 to 87 BCE. He is renowned for solidifying the central government, recruiting skilled officials, and making Confucianism the state ideology. Although years of foreign adventures, territorial expansion, and extravagant court expenditures left the empire in a state of unrest and the imperial treasury depleted, Wudi laid the foundation of a strong government for his successors.

Han Wudi, the fifth emperor of the Han dynasty (206 BCE–220 CE), was one of the most influential emperors in Chinese history. He consolidated the authority of the central government and expanded the territory of the dynasty. He named Confucianism the state ideology; it has influenced Chinese government and society ever since. His principles of recruiting government officials based on Confucian learning and on virtue and merit remained in use until 1905, at the close of the last imperial dynasty (the Qing, 1644–1911/12). He forged alliances, conducted diplomatic and military activities in Central Asia, established relationships with more than thirty kingdoms or tribes, and was instrumental in establishment of a new trade route, the Silk Roads, which connected China with the West. Until the advent of overseas travel during the sixteenth and seventeenth centuries, the Silk Roads connected East and West and facilitated the diffusion of commodities, food, culture, and technology.

Han Wudi's birth name was Liu Che. He was the fourth son of Emperor Jing, and his mother was a consort. In 150 BCE Jing named Han Wudi's mother, Lady Wang, empress and named Han Wudi his heir.

At age sixteen Han Wudi ascended to the throne, but his grandmother, Empress Dowager Dou, conducted the affairs of state. Empress Dowager Dou favored the early Han practice of Huang Lao, named after the legendary Huang Di (Yellow Emperor) and Laozi (Lao-tzu, Lao Tsu), author of the Daoist work *Daodejing* (Classic of the Way of Power). Huang Lao was characterized by frugality in government spending, light taxation, laissez-fair (a doctrine opposing government interference in economic affairs), and appeasement in foreign relations. After the death of Empress Dowager Dou in 135 BCE Han Wudi ruled and changed the course of government.

Han Wudi was a vigorous emperor who aspired to a strong dynasty and sought capable officials to assist him. He gave special exams on governance and personally read examinees' essays. He recruited gifted officials, including Dong Zhongshu and Gong Sunhong. The former became the spokesman for Han Confucianism, and the latter became chief minister and persuaded Wudi to establish an imperial university of Confucian learning.

Ironically scholars often call the emperor who made Confucianism the state ideology a "legalist." Legalism had been the ideology of the Qin dynasty (221–206 BCE). Legalists advocated strong rulers, a strong empire, and harsh punishment. Legalism was still viable in the early Han dynasty, and Wudi was influenced by it. He eliminated the power of China's princedoms and was relentless in executing officials, including chief ministers who broke the law or failed in their work. He also pursued a vigorous foreign policy and employed officials who favored harsh punishment. However, the early Han intellectual world was synthetic. Han Wudi substantially followed Confucian

practices. He observed Confucian ritual and music, promoted the Confucian virtue of filial piety (obedience to parents), and sent officials to assist people who were old, widowed, ill, or disabled. Moreover, despite initiating military campaigns, he did not increase taxes on the farming population. In his edicts he frequently revered Yao, the legendary Confucian sage ruler whom the Han emperors claimed as their ancestor. In addition, although Wudi was stern, he was fair. He accepted frank criticism and revered Jian, an outspoken Confucian-Daoist minister.

Wudi was strong and resolute but constrained by Confucianism and the Mandate of Heaven, which held that an emperor's rule is based on the blessing of heaven and that if an emperor rules unwisely, heaven will retract the mandate. They were devoted to Confucian ethical norms and a government for the people. Confucianism advocated a benevolent ruler, and Confucian officials were not unconditionally loyal to an emperor. Moreover, Han Confucianism (Confucianism of the Han dynasty which also absorbed non-Confucian elements) considered natural disasters to be warnings from heaven about flaws of the emperor and used such warnings to persuade emperors to reform.

In 124 BCE Han Wudi established an imperial university of Confucian learning, with fifty students studying from five learned Confucians, each specializing on a different Confucian classic. The university was designed to train Confucian officials, but it was based on merit. Graduates were required to pass a written exam before being admitted to a pool of officials-in-waiting. By the later Han dynasty the university had 300,000 students.

Han Wudi also promoted Confucian virtues in domestic affairs. Beginning in 134 BCE he ordered senior officials to recommend candidates who were known for their filial piety and integrity. The officials were responsible for their recommendations, and candidates were tested for qualification. Because Confucian learning and Confucian virtue were the avenues to officialdom, the most desirable career path in the empire, Confucian ideas took root in society. During the early Han dynasty, *The Classic of Filial Piety* also

appeared. Filial piety remains an important cultural value in China.

Wudi's predecessors had left him a large treasury from their frugal rule. However, Wudi's military campaigns soon emptied the treasury, and he tried various ways to raise money, including confiscating the lands of nobles and selling offices and titles. However, under the influence of Sang Hongyang, a merchant's son, Wudi increased state revenue by directly involving the government in business. The government monopolized the production of money (coins), iron, salt, and liquor, thus bringing in revenue. Wudi also directed the government to buy grain in regions with full harvests and to sell grain in regions with a shortage. This policy turned a profit for the state, balanced the price of grain, and relieved famine. The state also profited from a heavy tax on merchants. In addition to taxing commodities, Han Wudi taxed carts and boats.

The influence of Han Wudi's state monopoly was far reaching; later Chinese emperors often resorted to the monopoly to meet extreme fiscal difficulties, bringing in revenue without increasing taxes. The monopoly, however, was not without opposition. In 81 BCE, shortly after the death of Wudi, a group of people criticized the state monopoly in a court debate. Wudi's fiscal policies were in sharp contrast with those of the previous sixty years of the early Han dynasty, but in the debate the government's views prevailed.

Han Wudi made many other innovations, such as proclaiming a new calendar. However, his economic policies were most innovative and, to some extent, were comparable with modern state enterprises (in some countries) on vital industrial resources such as electricity and petroleum.

About 200 BCE the Xiongnu, a nomadic Turkish-speaking people under the rule of Maodun, had established a large federation from the Aral Sea to the Huang (Yellow) Sea, just north of Han territory. Unable to confront Maodun, the early Han rulers had sent him gifts and married a Han Princess to him; but they had not always been able to prevent Maodun or his successor from pillaging northern China. In order

Hold faithfulness and sincerity as first principles. • Confucius (551–479 BCE)

to confront the Xiongnu, Han Wudi in 139 BCE sent an envoy, Zhang Qian, to Central Asia to seek an alliance with the Yuezhi people, who earlier had been expelled from their homeland by the Xiongnu. Zhang Qian was captured by the Xiongnu and lived there for ten years before finally reaching the Yuezhi. However, by then the Yuezhi were no longer interested in forming an alliance to fight the Xiongnu. Zhang Qian, however, brought back information about new regions and a possible route to India. Subsequently Wudi first sent envoys and later troops, leading to the eventual establishment of the Silk Roads.

Beginning in 133 BCE Wudi took the offensive against the Xiongnu. The wars were long and costly, but the Han army was victorious. Wudi's generals expelled the Xiongnu from Ordos, Inner Mongolia, Kansu, and Chinese Turkestan and greatly expanded Han territory. Wudi established military colonies and instituted a system whereby native rulers were allowed to retain their autonomy but became vassals. This arrangement became common in Chinese foreign relations until the mid-nineteenth century. Wudi's army also incorporated northern Korea and northern Vietnam. Indeed, most of his reign was marked by military campaigns. He died at age sixty-nine and was buried in Maoling near modern Xi'an. After his death he was known as "Wudi, the martial emperor," although he never led an army; he instead employed gifted generals.

Han Wudi laid the foundation of a strong empire for his Han dynasty posterity. His establishment of a Confucian bureaucracy with merit-based recruitment (a combination of recommendation and examination) began a system of responsible rulers and officials that has lasted for more than two thousand years. His promotion of Confucian virtue and learning made Confucianism a prevailing influence in China and in

other East Asian states. Through his military campaigns against the Xiongnu he opened a connection between East and West, facilitating trade and cultural diffusion.

Hanseatic League

In the mid-twelfth century, without navies to protect cargoes or international agencies to regulate tariffs, northern German cities formed the Hanseatic League in an effort to ensure that ports were safely maintained and tariff agreements set. The league controlled increasingly wide trading routes but declined in the early sixteenth century with the disappearance of local herring fisheries and the growth of English and Dutch merchant marines.

The Hanseatic League was a federation of merchant cities that formed in northern Germany during the middle of the twelfth century and dominated trade in northern Europe for the next two centuries with its economic policies. The league derived its name from the German word *hansa*, an association or group of merchants who specialized in trade with foreign cities or countries. The unstable and dangerous nature of mercantile life in the late medieval period, combined with the lack of organized protection provided to merchants by their own government, encouraged traders to work together for safety. These alliances, which originally started out between merchants from the same town, soon grew into larger associations and leagues between neighboring towns.

In antiquity, the most cost effective way to transport commercial goods was over water, and cities located on rivers or the coast had a natural advantage over interior cities. In the late eleventh and early twelfth centuries, cities in northern Germany became important commercial centers due to their position on trade network routes that allowed them to serve as conduits for commercial goods traveling to and from southern Europe over the North and Baltic seas. This

trading network soon increased in scope to include goods moving west to England and east into Russia. The weak and decentralized government of Germany during the eleventh and twelfth centuries was able to provide little assistance or protection for its traders, and this lack of governmental support forced individual merchants and commercial cities to create their own ties and associations for mutual protection.

In 1241 Lübeck and Hamburg strengthened the existing commercial ties linking the two cities with a treaty designed to protect their mutual commercial traffic. Lübeck's chief industry in the twelfth century was the exportation of herring caught at nearby fisheries. Due to existing religious dietary restrictions

At the beginning of the sixteenth century the herring industry disappeared in Germany, and the league declined in power and membership.

on eating meat on certain days, fish had become an integral part of the Christian diet, and Lübeck had capitalized on a growing demand for its fish in central Europe. Hamburg was essential to Lübeck's fishing industry, since it provided Lübeck with the salt needed for salting and drying of the herring, which allowed it to be safely transported without spoiling. To facilitate this trade between their cities they constructed a canal that connected the two cities. To protect this trade, they further reinforced their economic ties with the treaty.

This initial association between Lübeck and Hamburg slowly grew into a larger league as other cities joined. While the majority of the league's members were from northern Germany, it did include cities in Holland and Poland. At the height of its power, the federation consisted of over 165 member cities. The league originally functioned only to facilitate

common commercial ventures, not for political or religious purposes. Each member city's merchant association could send delegates, if it wished, to the league's formal meetings (diets), which were held at Lübeck to discuss economic policies. The attending delegates took the diet's economic decisions back to their city for their local merchant association to accept or reject. The Hanseatic League's economic strategy was designed to protect the trading privileges of its members, to open new markets for exploitation, and to create monopolies wherever possible. The economic success of the league's members soon led it into political conflict with the king of Denmark, Valdemar IV, over control of local herring fisheries. After an initial setback, the league defeated the king and forced him to sign the Treaty of Stralsund in 1370. This treaty made sweeping economic concessions to the Hanseatic

Hans Holbein the Younger, *Portrait of Georg Giese [Giese]* (1532). Giese, from Danzig, was a Hanseatic League merchant at the Steelyard, the Hanse branch in London.

League and gave the member cities privileged trading rights, including free trade in Denmark. This control over trade in northern Europe continued into the fifteenth century until an unsuccessful war with Holland forced the Hanseatic League to sign the Peace of Copenhagen in 1441, breaking the league's hold on the Baltic Sea.

By the beginning of the sixteenth century, the league had begun a slow decline in both its power and membership. The disappearance of the local herring fisheries and the growth of the English and Dutch merchant marines resulted in increased competition, which the league was unable to overcome, and soon led to the loss of exclusive trading markets for Hanseatic members. While the league was never formally dissolved, its last official meeting was held in 1669.

Harappan State and Indus Civilization

The Indus was the earliest civilization of South Asia, contemporaneous with Bronze Age Sumer, Egypt, and China. The Indus participated in what is now called the Third Millennium Middle Asian Interaction Sphere, which linked its people to the Mediterranean and from Central Asia to the Arabian Gulf in an important trading network. Scholars today debate the reasons why most Indus cities were abandoned by 1900 BCE.

The earliest civilization of South Asia is called the Indus, or Harappan, civilization. This ancient culture arose on the plains and in the mountains of the greater Indus Valley of Pakistan and northwestern India in the middle of the third millennium BCE (c. 2500–1900 BCE). The Indus civilization takes its place in world history as the first of ancient India's cities and was contemporaneous with those of the Bronze Age peoples of Sumer, dynastic Egypt, and China.

The Indus peoples were for the most part farmers, herders, craftsmen, and traders. They inhabited at least five cities, the best known of which are Mohenjo Daro and Harappa but which also include Dholavira, Ganweriwala, and Rakhigarhi. Mohenjo Daro and Harappa are the largest of the cities, each being about 100 hectares. (The other cities are slightly smaller; between 65 and 80 hectares.) Archaeologists believe that Mohenjo Daro and Harappa each had a population of about twenty thousand people.

The Indus civilization was by far the largest of the Bronze Age civilizations of Asia. It covered about a million square kilometers, extending from the present-day Pakistan-Iran border in the west to the coast of southern Gujarat in the east. The northern

limit for the principal habitations is the Siwalik Range of the Punjab, although there is an outlying Indus site (Shortughai) in northern Afghanistan, on the Amu Dar'ya River. In an effort to deal with the cultural geography of the Indus civilization, scholars have divided their territory into domains (geographical and cultural subregions) that may possibly have political significance.

Early Harappan Period and Urban Transformation

The beginnings of the Indus civilization are still not well understood. During an early Harappan period (c. 3200–2600 BCE) there were four roughly contemporaneous archaeological cultures (Kot Dijian, Amri-Nal, Damb Sadaat, and Sothi-Siswal) without large settlements or strong signs of social stratification. No remarkable degree of craft specialization existed during this period. At about 2600–2500 BCE a transitional stage occurred between the early Harappan and Indus civilization, during which most of the complex sociocultural institutions of the Indus civilization came together.

The urbanization that characterizes these peoples developed rather suddenly, over a period of about a hundred years. After a long period of gradual growth and change, the peoples of the greater Indus Valley created cities, a writing system, and a class-stratified society. Of course, some parts of older traditions of the greater Indus region survived. It is clear that there was little change in subsistence and the sociocultural, economic, and political balance between farmers and pastoralists, for example. This was also the time

Brick altars in modern India, once used for sacrifices, have origins in the ancient Indus Valley. Photo by Klaus Klostermaier.

during which the Indus ideology, or world view, began to emerge. It had a rather strong sense of nihilism to it. (Nihilism can be a negative philosophy, as it is often, but not always, associated with violence.) Some scholars suggest that the nihilism of the Indus civilization was in many ways a new beginning for its peoples, that they had turned aside many of their roots. Thus the Indus civilization can be said to represent a renaissance of sorts. (See Possehl 2002, 55–61 for more on this theme in Indus archaeology.) Water and cleanliness were powerful forces in the Indus ideology, such that the society valued both the physical property of water to remove dirt and oils from the skin but also the symbolic act of washing and generalized purity as well.

The ancient cities of the Indus were built in riverine settings: on the lower Indus River (Mohenjo Daro), the Ravi River in the Punjab (Harappa), and the Ghaggar-Hakra River (Ganweriwala and Rakhi-garhi). Dholavira may be an exception to this; today it is on an island in what is called the Rann of Kachchh, a large salt marsh above the Gulf of Kachchh. We do not know if the shallow Rann of today was an arm of the sea in the third millennium, but the Rann most certainly would have been fed in part by the waters of the Indus, so in a sense Dholavira too can be said to have a riverine setting.

The land was quite different in the third millennium, when the now-dry Ghaggar-Hakra was larger and the rolling uplands between the rivers of the Punjab were unirrigated scrub grasslands. Tree and grass cover were also probably better. But there were also constants—the summer monsoon, for example. The wheat and barley crops of the Punjab, Sind, and Baluchistan benefited from the winter rainfall coming across the Iranian Plateau from the Mediterranean, just as they do today.

The Cities of Mohenjo Daro and Harappa

Mohenjo Daro is a splendidly preserved ancient city. It was planned from the start, and was, at least for the most part, built in the middle centuries of the third millennium. It is constructed from baked brick, which is why it has survived so well. There are two parts to the city. A small, elevated artificial mound was situated on the west. This is now called the Mound of the Great Bath, because of the presence of a ritual bathing tank at just about its geographical center. The Lower Town, where most of the people lived and worked, was laid out in a grid, with major thoroughfares running north-south and east-west. Multiroom buildings that were probably

In the great books of India, an empire spoke to us, nothing small or unworthy, but large, serene, consistent, the voice of an old intelligence, which in another age and climate had pondered and thus disposed of the questions that exercise us. • **Ralph Waldo Emerson (1803–1882)**

also multistoried lined these streets. The private houses were generally provided with bathing facilities that were connected to a civic drainage system. These were specifically bathing facilities; they were not privies.

Harappa is located in the West Punjab, in Pakistan, on the southern bank of the Ravi River 650 kilometers northeast of Mohenjo Daro. Harappa is the name of the modern village adjacent to the mounds, and is not the city's ancient name. Unlike Mohenjo Daro, Harappa was a well-established settlement before the advent of the Indus civilization. There were villages there as early as 4000–3200 BCE as well as during the early Harappan period. Harappa is also a place

where the transition from early Harappan to mature Harappan civilization can be documented, so it is a very important site for archaeologists. There is also a small post-Indus settlement and cemetery there, of the so-called Cemetery H culture.

Harappa has been divided into several areas. The AB Mound, also called the High Mound, is somewhat like the Mound of the Great Bath at Mohenjo Daro, but lacks a bath, as far as archaeologists can tell. Mound F to the north has a large building that may well be a warehouse. It is near threshing and husking facilities for the processing of food grains. The southern part of the site is known as Mound E, with the adjacent ET area, an area of habitation and craft

activities. Harappa also has the largest of the cemeteries known from the Indus civilization.

Indus Technologies and Lifeways

The Indus peoples had a writing system, which was rendered in pictographic form on a range of objects. The best known of these are the Indus stamp seals with writing and an animal device. The Indus script remains undeciphered, in spite of many claims to the contrary.

Farming and herding were important occupations for the Indus peoples. The principal food grains were barley and wheat. They also cultivated at least two forms of leguminous seed (the chickpea and the field pea), mustard, sesame, cotton, grapes, and dates. The evidence for the cultivation

of rice during the Indus civilization is ambiguous, but it is possible that Indus peoples cultivated rice. Indus peoples were cattle keepers, and the remains of the zebu, the humped Indian breed, are consistently above 50 percent of the bones found in an archaeological excavation. Cattle imagery is also prominent; it is clear that cattle were the most important animals in the culture and probably the principal form of wealth. The Indus also kept water buffalo, sheep, goats, and pigs. Fish, both marine and freshwater, were traded over wide areas.

The Indus peoples were skilled craftsmen and applied themselves to their trades with great vigor. They were technological innovators, inventing processes that allowed them to etch and drill long, hard stones such as carnelian, to make stoneware and ceramics, and to smelt, refine, and process a variety of metals. Their pottery was fashioned using a number of forming techniques, often in multiple parts that were welded together prior to firing. They were skilled at bead making, with their long, barrel-shaped carnelian beads a specialty. Shells, especially the maritime conch, were made into bangles, ladles, and other objects, and were inlaid in objects for decoration.

Cultural Interaction across Afro-Eurasia

World history has been enriched by the Indus peoples, who participated in what has come to be called the Third Millennium Middle Asian Interaction Sphere, which linked peoples from the Indus to the Mediterranean and from Central Asia to the Arabian Gulf in an important trading network. This interaction has deep historical roots and began much earlier than the Indus civilization, but was at its peak during the second half of the third millennium. Sea trade with Mesopotamia through the Arabian Gulf was a part of this network and can be documented in both written and archaeological records. According to Mesopotamian cuneiform texts, the products that the Indus peoples supplied to Mesopotamia were carnelian, lapis lazuli, pearls, various exotic woods, fresh dates, copper, and gold. Not clearly documented are the products traded

to the Indus, but they may have been perishables such as food products, oils, and cloth.

Two themes that appear on Indus seals have parallels in Sumerian mythology. The first is shown on a seal from Mohenjo Daro with a half-human female, half-bull, monster attacking a horned tiger. This is widely interpreted as portraying the story of the Mesopotamian goddess Aruru, who created the monster to do combat with the hero Gilgamesh, though the monster ultimately became Gilgamesh's ally and fought with Gilgamesh against wild animals. The second motif is a well-documented Mesopotamian combat scene, with Gilgamesh fighting off rampant animals on either side.

A male deity, usually shown with bull or water buffalo horns, is central in Indus religion. He is paired with a number of different female images. The plant and animal imagery of the Indus civilization can be seen as representing specific aspects of this great heaven-earth, male-female duality. There are many portrayals of composite animals, some with three heads on one body, human torsos on four legged bodies, men with bull's heads (like the Minoan Minotaur), tigers with horns, unicorns with elephant trunks, and unicorns growing out of trees. There is no good evidence for fire worship, as seen in later Vedic India.

A seal from the Indus site of Chanhudaro, just south of Mohenjo Daro, has a representation of a bull sexually ravishing a prostrate human female. The archaeologist F. R. Allchin interprets this as representing the duality of heaven (the bull) and earth (the female), a theme that can be understood by reference to the creation myths found in the Rig Veda and Atharva Veda. This is perhaps our best evidence for a connection between the Indus civilization and later, historical, India.

The Transformation of Indus Civilization

What happened to the ancient cities and peoples of the Indus? Mohenjo Daro was largely abandoned by 1900 BCE. The same is true for the other four

Indus cities, although a small settlement remained at Harappa—the so-called Cemetery H people. Older theories, which hold that the cities and civilization were destroyed by invading Aryan tribes (as depicted in the Rig Veda), make very little sense since there is no evidence for the sacking of any of the Indus settlements. Also, the date of the transformation of the Indus civilization around 2100–1900 BCE and the date of the Vedic texts (c. 1000 BCE) don't agree. The proposition that a natural dam formed across the Indus River in Sind and flooded out the civilization has been widely critiqued and is not viable.

It is apparent from the excavations at urban centers as well as from regional surveys that at the opening of the second millennium Indus settlements in Sind and Baluchistan had been widely abandoned. Table 1 provides a summary by region of the substantive data comparing Indus civilization and the period following the transformation, generally called the Indus post-urban civilization.

The figures in table 1 would seem to indicate that it is still viable to speak of the “eclipse of the Indus civilization” in Sind and Baluchistan, but in other

regions, notably in the East and to a lesser degree in Saurashtra (present-day Gujarat), the history of the culture change was different. In these areas there were strong lines of continuity through the early centuries of the second millennium with little, if any, of the trauma that affected Sind and Baluchistan. The stark image of Baluchistan in the second millennium represents a clear challenge for field archaeology, because it does not seem reasonable to presume that the entire area was deserted at that time.

Scholars have proposed that the process responsible for transforming this once grand civilization involved changes in the Indus ideology, possibly its abandonment. For example, one of the clearer loci of culture change was in the cities, those settlements and institutions most closely associated with sociocultural complexity. There, craftsmen's technological virtuosity was severely compromised, and the obvious traces of the symbolic uses of water disappear. But in some places the transformation of Indus civilization was not a traumatic event. Scholars speculate on the reasons for this possible abandonment of Indus ideology, but no consensus has yet been reached.

Table 1.

Indus Civilization and Indus Post-Urban Civilization

Urban life in the subcontinent begins with the Indus civilization, and this is its most obvious contribution to world history. Some suggestion of continuities between the Indus civilization and later historical times exist, but these are not yet well defined. The famous Proto-Shiva seal from Mohenjo Daro shows us that yoga, or ritual discipline, has its roots in the Indus. There is also strong continuity in farming and herding, and the seasonal pattern of life. It is clear that the special, and important, role of cattle in ancient Indian society has its roots in the Indus too. Large-scale interregional trade (by both land and sea) had its beginnings in the Indus civilization. The Indus peoples in that sense anticipated the later Silk Roads with the Third Millennium Middle Asian Interaction Sphere.

Harun al-Rashid

(766?–809 CE)

FIFTH CALIPH OF THE ABBASID DYNASTY

From 786 to 809 CE Harun al-Rashid ruled as the Abbasid dynasty's fifth caliphate. It was a culturally dynamic period marked by important developments in Islamic jurisprudence, philosophy (with the continued translation of Greek works), literature (with the integration of Persian influences), and personal piety (with the emergence of early Sufism). Al-Rashid's reign can be characterized as a mixture of military aggression and pragmatic diplomacy.

Harun al-Rashid ibn Muhammad al-Mahdi ibn al-Mansur al-'Abbasi reigned as "al-Rashid," the fifth caliph of the Abbasid dynasty (749/50–1258), from 786 to 809 CE. His reign was pivotal in the administrative and institutional development of the caliphate, marking in many senses the zenith which presaged its decline. His contacts with the Latin West, and his relationship to *The One Thousand and One Nights*, made him a famous, if overly romanticized, figure.

Harun was likely born in al-Rayy (modern Shahr-e-Rey in Iran) in February 766 CE, the third son of the caliph al-Mahdi (reigned 775–785 CE) by a slave from Yemen named al-Khayzurun. Although he grew up in the luxury of the increasingly decadent caliphal court, young Harun gained military and administrative experience, at least nominally, in expeditions against Byzantium and as governor of the western provinces. His candidature for caliph was stage-managed by his mother and Yahya ibn Khalid (d. 805 CE), a scion of the powerful Barmakid family. He suffered under the rule of his brother al-Hadi (reigned 785–786 CE), whose death under suspicious circumstances left the way clear for Harun's succession. As caliph he assumed the honorific al-Rashid ("the Rightly Guided").

The Barmakids remained the real power behind the throne until 803, by which time al-Rashid had established an independent administrative regime based on palace slaves and clients who owed their loyalty to him alone—a pattern that was to be followed in future caliphates. Under al-Rashid's rule, the caliphate was torn by forces of decentralization, characterized by the loss or impending loss of Africa,

Khorasan (present-day northeastern Iran), and Yemen. Much of this was due to factors beyond the ruler's control, although some of his policies, including dividing his realms among his chief heirs, hastened the subsequent decline.

The period comprising his rule was culturally dynamic, marked by important developments in Islamic jurisprudence (including the development of Malikism, one of the four main schools of jurisprudence), philosophy (with the continued translation of Greek works), literature (with the integration of Persian influences) and personal piety (with the emergence of early Sufism).

Al-Rashid's relationship with the Eastern Roman Empire (Byzantium) was characterized by a mixture of military aggression and pragmatic diplomacy. Byzantium made a suitable object for the regular raiding that a caliph was ideally expected to carry out against the non-Muslim world, and al-Rashid himself led many such missions. Although these did not result in permanent territorial gains, they forced the Empress Irene (reigned 780–802 CE), under pressure from the Bulgarians, to seek a peace treaty. Al-Rashid was compelled to accept given the threat of the Khazars, Turkic tribal allies of Byzantium who controlled European Russia.

In 798 Charlemagne (742?–814 CE), the Frankish king and aspirant to the title of Holy Roman Emperor, sent an embassy to Baghdad, proposing an alliance against Irene. In 801 al-Rashid reciprocated, sending

an embassy to Aachen under the direction of a Jewish merchant named Isaac and bearing a number of notable gifts, including a water clock and an elephant. No practicable alliance resulted, but certain general accords were reached concerning trade and travel. In 806, however, a spectacular Abbasid military victory against Irene's usurper, Nicephorus, forced Byzantium into humiliating submission.

Al-Rashid's rival in the far west, the Umayyad emirate of al-Andalus (on the Iberian Peninsula), also benefited from contacts with the Abbasid caliphate, primarily in matters of culture and technology. Al-Rashid's patronage of the musical innovator Ziryab prompted envy in the Ziryab's master, the head court musician Ishaq al-Mawsili, who orchestrated Ziryab's exile. In 821 CE Ziryab arrived in Cordoba, where he rapidly became a favorite of the emir and an arbiter of taste among the Andalusí aristocracy, single-handedly revolutionizing western Mediterranean cooking, poetry, music, and dress habits.

The Abbasids had long-standing trade and diplomatic relations with China, both via the Indian Ocean and overland, through the mediation of Jewish merchants, the Radhans. From the mid-eighth century, China and the caliphate were political rivals in Transoxiana (northeast of Khorasan), and Muslims began to intervene occasionally in Chinese internal power struggles. A regular series of diplomatic missions had been sent to the Tang emperors since the early 700s; this was continued under al-Rashid.

The Thousand and One Nights, a collection of folktales and parables drawn from Arabic, Persian, and Indian traditions, several of which feature al-Rashid as a leading character, are the primary source of the caliph's image in the modern West. The first European-language version appeared in French in 1704 and was eventually followed by Richard Burton's *The Arabian Nights* (1885–1888). Thanks largely to this, al-Rashid enjoys a reputation as a cultured, wise, and effective ruler, an assessment which does not necessarily conform to the historical evidence.

Hatshepsut

(REIGNED c. 1503–c. 1482 BCE)

QUEEN OF EGYPT

Historians debate the significance of Hatshepsut, one of few female rulers of ancient Egypt. Traditionally she has been viewed as a schemer who usurped the throne, while more recent scholarship acknowledges the complex difficulties she would have faced as a female ruler some 3,500 years ago. Her seemingly uninhibited access to natural and human resources, however, allowed her to engage in a substantial building program throughout Egypt.

Hatshepsut was queen of ancient Egypt during the eighteenth dynasty (c. 1540–c. 1307 BCE). She was the daughter of pharaoh Thutmose I, half sister and wife of Thutmose II, and stepmother of Thutmose III, with whom she ruled over Egypt for a period of about twenty years. Although the precise nature and circumstances of her rule and subsequent demise are unclear, she is one of the most outstanding and controversial figures in the long history of pharaonic Egypt.

With only few female examples to follow, she ascended the throne of Egypt, first as regent on behalf of her young stepson Thutmose III, the official successor to Thutmose II, and subsequently had herself crowned as ruler of Egypt with all necessary royal titles and regalia. This she was able to legitimize in two ways. First, there was her pure royal bloodline and fine genealogy, which are well expressed in her original queenly titles before she assumed kingship: “daughter of the king,” “sister of the king,” “the god’s wife,” “great royal wife,” and “mistress of the Two Lands” (Seipel 1977, 1045; Bryan 2000, 238). Second, she presented herself as the explicitly designated heir to her father Thutmose I, a political claim that

was theologically reinforced by the story of her divine conception and birth to the god Amun, artistically depicted on the walls of her funerary temple in Deir el-Bahari (western Thebes).

The political success of her otherwise conservative and traditional reign can be measured by a relatively stable foreign policy, active interaction with Egypt’s neighbors Nubia (present-day northern Sudan and southern Egypt) and the Levant (present-day Syria and Lebanon, and her seemingly uninhibited access to natural and human resources, which allowed her to engage in a substantial building program throughout

Funerary temple of Queen Hatshepsut, Deir el Bahari, Thebes, Egypt (dating to c. 1482 BCE). The story of Hatshepsut’s divine conception and birth to the god Amun is depicted on the walls.

Now my heart turns this way and that, as I think what the people say. Those who shall see my monuments in years to come and who shall speak of what I have done. • **Attributed to Hatshepsut (r. c. 1503–c. 1482 BCE).**

Egypt. The great temple to her divine father Amun at Karnak received particularly generous additions in form of chapels, shrines, obelisks, and a monumental gateway (the Eighth Pylon). Her own funerary temple at Deir el-Bahari has been described as “the most complete statement in material form of her reign” (Bryan 2000, 241) and is one of the finest examples of ancient Egyptian architecture, combining elements of previous periods with unique artistic representations of her time. Famous is the detailed depiction of her naval expedition to the land of Punt in East Africa, which brought back such exotic goods as wild animals and live incense trees. Also represented is the transport of two monumental obelisks from the granite quarries in Aswan to the temple at Karnak on a large barge, which even by today’s standards represents a major engineering feat, given their estimated weight of about 144 metric tons each. Her court obviously enjoyed a rule of affluence and generous economic support from their queen, which is reflected in an increase in wealthy and richly decorated private tombs of officials and the large number of private statues of such individuals produced during her reign.

Interestingly, numerous art representations of her time document how she slowly abandoned her feminine features in favor of more male—that is, kingly—attributes, including beard, bare and masculine upper torso, and kilt, which has often been interpreted by some scholars as a desperate attempt for political acceptance as ruler. That her rule may not have been fully endorsed by her contemporaries is supported by her successor Thutmose III’s deliberate destruction of her monuments and radical efforts to erase her from public memory, although this evidently happened only decades after her death. Other evidence that her rule may not have been fully endorsed includes inscriptions from her funerary temple, in

which she expressly requests her officials’ loyalty and support.

There is no record of the causes and circumstances of Hatshepsut’s death and no royal mummy has as yet been attributed to her, which could provide forensic evidence for the nature of her death. There is also considerable scholarly confusion over the place of her burial, as there exist at least three sarcophagi and two tombs, one in the Valley of the Queens (probably made during her time as wife of Thutmose II), the other in the Valley of the Kings near Luxor.

Hatshepsut was one of the very few female rulers of Egypt, and her historical significance has been widely debated by scholars. She has traditionally been viewed as a schemer who usurped the throne and had a disastrous reign. More recent scholarship views her as a “remarkable woman” (Tyldesley 1996, 1), acknowledging the complex difficulties she would have faced as a female ruler some 3,500 years ago.

Just as she might have been subjected to the prejudices of a predominantly male royal court culture during and after her lifetime, Hatshepsut’s historiography has equally suffered from the tangle, underlying gender biases expressed in nineteenth- and twentieth-century scholarship, which may make any historiographical assertions about her rule more revealing of the prejudices afflicting scholarship at different points in time than of the actual nature and significance of Hatshepsut’s rule on the throne of the pharaohs.

Hausa States

Archaeologists and historians believe that the Hausa States emerged around the late 900s CE in present-day Nigeria; by the eleventh century their walled towns were flourishing centers of trade. High levels of education, accomplishments in crafts and trade, and civic organization characterized the Hausa and left a lasting legacy; the Hausa are active in the politics of present-day Nigeria.

The foundation myth of the Hausa peoples says that the seven “true” Hausa States were founded by the seven sons of Bayajidda, who had come from the east (some say from Baghdad) to the state of Daura (in present-day northern Nigeria). Bayajidda had won the hand of the queen of Daura in marriage by slaying an evil serpent; she was the mother of the seven sons. The seven states these sons founded were Kano, Zazzau (Zaria), Gobir, Katsina, Rano, Daura, and Biram. Legend also has it that Bayajidda had other sons by a concubine; these sons are the supposed founders of the “illegitimate” Hausa states of Zamfara, Kebbi, Nupe, Gwari, Yauri, Yoruba, and Kororofa.

Early History

Archaeologists and historians believe that the Hausa States emerged between the late 900s CE and the early 1200s. Hausa towns are known for their walls, which enclose not only houses but farmland as well. This custom of building walls was maintained as the size of the enclosed settlement grew.

By the eleventh century, these walled city-states were flourishing centers of trade. Kano, Katsina, and Gobir, for example, had developed their

caravan trade and services. Each state also had certain specialties—Kano specialized in leather goods and weaving, for example, while Zazzau specialized in the slave trade. In addition, they drew on the wealth of their rural areas, which produced millet, sorghum, sugarcane, and cotton. Cattle were also plentiful. However, their prosperity put them under steady stress from Songhai and Kanem-Borno, their neighbors to the west and east. The Hausa States paid tribute to the latter empire, and, in turn, fought with their other neighbors, conducting slave raids and open warfare with the Jukun and Yoruba states.

Islam and the Hausa States

Although Islam was known in the Hausa States by the eleventh century, tradition credits its introduction to an Islamic missionary who came from Bornu in the fifteenth century. The elite accepted the new religion first, practicing it while continuing to adhere to older religious traditions. Islam offered the elite a means for organizing an efficient state and promoting education. It also tied the rulers and those who received an Islamic education into a vast Islamic trading network and gave them a language used in the network, Arabic. The Islamic connection strengthened ties with North Africa that already existed through trade (the Hausa States were a southern terminus of the trans-Saharan trade route). These ties were also supported by pilgrimages to Mecca.

At about the same time that Islam fully penetrated the ruling class, Fulani pastoralists came to Hausaland. Muslim Fulani, who had adopted Islam in the area now known as Senegal, settled in Hausa cities in the thirteenth century and began to intermarry

when the Fulani religious leader Usman dan Fodio (1754–1817) waged jihad among the Hausa States, seeking to convert the common people to Islam and to purify the practice of the faith among the elite. Usman dan Fodio's Sokoto caliphate, established around 1808, included the Hausa States, who remained part of Sokoto until Sokoto was defeated by the British in 1903. The high levels of education, accomplishments in crafts and trade, and civil organization that characterized the Hausa States left a lasting legacy, however, and the Hausa (many of whom live in present-day northern Nigeria) are active in the Nigerian politics. Today the Hausa also live in southern Niger, as well as in parts of Ghana and Togo.

with Hausa. These Hausa-Fulani became an educated religious elite, crucial to Hausa rulers because of their knowledge of government, law, and education.

Later History

In the thirteenth and fourteenth centuries, there was a loose alliance of the seven Hausa states, based on the Hausa language and common customs as well as the modified Islam practiced by the ruling class. The ruler of each state, the emir or sarki, collected taxes from the various guilds within the state. These commercial guilds were self-regulating and loyal to the emir, who offered them protection. The guilds' members were commoners, both men and women depending upon the craft. Slaves maintained the cities' walls and grew the food.

From the early sixteenth century, the Bornu state in the Lake Chad basin area grew increasingly powerful; it brought the Hausa States under its control, and they remained subject to Bornu through the eighteenth century. Then at the dawn of the nineteenth century, Bornu's control was overthrown

Henry the Navigator

(1394–1460)

PORTUGUESE PRINCE

The Portuguese prince Henry (1394–1460)—the epithet “Navigator” was not bestowed upon him until the nineteenth century—is best remembered for the voyages he sponsored to the West African coast, one of which resulted in the discovery of a sea route to India. But his settlements and the ensuing economic development in Madeira and the Azores held more immediate benefits for him and for Portugal as a whole.

Henry the Navigator was one of the earliest and most vigorous proponents of European overseas expansion and exploration. Prince Henry (Dom Henrique) was the third son of King João I of Portugal and his queen, Philippa of Lancaster, of England’s house of Plantagenet. Often credited with founding a school of navigation at Sagres in southwest Portugal, Henry was not actually a mariner—he probably never sailed farther than northern Morocco—and he had no school at Sagres or anywhere else. A strong advocate of the church militant, in 1415 he took part in the capture of the Moroccan port of Ceuta, a place of little economic or strategic significance that proved costly to maintain but impossible to surrender without loss of face. A subsequent attack on Tangier failed, and Henry eventually turned to more commercial pursuits that took his caravels into the archipelagoes of the eastern Atlantic and along the Guinea coast of West Africa. Although the chief impetus for these voyages was commercial, Henry was also motivated by an abiding belief in the medieval concepts of just war and crusade, and an obligation to preach the true faith to heathens and crusade against heretics and Muslims.

Henry’s overseas interests began when he was made donatory (lord-proprietor) of Madeira in 1433, whereupon he began to organize the colonization and exploitation of the islands for lumber, wine, and sugar. He likewise began the settlement of the Azores in 1439. Henry’s interest in the coast of Africa derived from his failed efforts to establish Portuguese control of the Canary Islands, which were claimed by Castile. In the 1420s, Henry began sponsoring a series of voyages down the west coast of Africa in the hope of establishing a kingdom rich in slaves, gold, and the produce of the coastal fisheries. By 1434, the Portuguese knew the coast of Africa as far south as Cape Bojador, in the latitude of the Canaries—widely believed to be the southern limit of safe navigation. By 1445, a large expedition (reportedly numbering 26 ships) sailed for Río de Oro, and a few vessels reached the Senegal River and Cape Verde even farther south. Three years later a fort was built on the island of Arguin (in Mauritania), from which the Portuguese conducted a lucrative trade in ivory, gold, and slaves. By Henry’s death twelve years later, the Portuguese had explored about 4,000 kilometers of the coast of West Africa, including expeditions up the Senegal, Gambia, and other rivers, and they had discovered the Cape Verde Islands.

Henry’s sponsorship of these voyages was predicated on returns, and he set clear objectives for his captains, regulating the distances to be covered and ensuring that details about the navigation and geography of the coast, trade goods, and local languages were collected. One result of these African voyages was the discovery of a sea route to India, but neither Henry nor any of his contemporaries had any

He took his first step when he was twenty-five years old and built himself a modest house on the southern tip of Portugal, where he could stand with Europe at his back, Africa before him, and the Unknown crashing against the boundaries in between. • **Jean Fritz (b. 1915)**

Prince Henry was less of a navigator than an avid sponsor of voyages to the West African coast.

such end in mind. They did, however, believe they could reach the lands of Prester John, the Ethiopian Christian king of medieval legend and a potential ally in any prospective crusade against Islam. The route there was thought to be via the Sinus Aethiopicus, a hypothetical African gulf first described in the fourteenth century, from the head of which Ethiopia was thought to be a short march overland. The possibility that a sea route around Africa to the Indies might exist took hold only after the Portuguese had passed Cape Verde and turned east into the Gulf of Guinea.

Although the economic development of Madeira and the Azores held more immediate benefits for him and for Portugal as a whole, Henry is best remembered for his sponsorship of the African voyages, thanks especially to the flattering chronicle of his

contemporary, Gomes Eanes de Zurara. More reliable is the account by the Venetian Alvise Cadamosto, who made two voyages under Henry's auspices in 1455 and 1456. On the strength of Henry's Plantagenet ancestry, Samuel Purchas also claimed that he was the "true foundation of Greatnesse, not of Portugall alone, but . . . especially of these Heroike endeavours of the English" (Russell 2001, 1). The more extravagant epithet, "Navigator," was not bestowed until the nineteenth century. Another more immediate legacy is the indirect connection between Henry and Christopher Columbus. In 1446, Henry assigned the administration of Porto Santo in the Madeiras to Bartolomeu Perestrelo, who had grown up in Henry's household and who probably advised him on the subject of Atlantic navigation. Perestrelo's daughter Felipa Muniz married Columbus, who thereby received her father's maps and papers.

Herodotus (c. 484–425 BCE) was the first Greek to write a history of the world as he knew it. The central topic in his nine-book-long *Histories* examined conflict and war among Greeks and Persians. He gathered information by traveling, asking questions, and comparing the stories he was told; although he sought the truth, he often repeated what he heard, warning his readers that he did not personally believe it.

Herodotus was the founder of the Greek historiographic (relating to the writing of history) tradition. Although earlier writers may have written books dealing with historical topics, Herodotus was the first to write in Greek a long prose work that had the purpose of narrating and explaining a complex historical event. The tradition of historical writing that began with the publication of Herodotus's work during the late fifth century BCE extended to the end of antiquity and provides the principal source of information for the history of the Mediterranean Sea basin from the sixth century BCE to the seventh century CE.

No ancient biography of Herodotus survives. The only sources for his life are his work and an article in a tenth-century CE Byzantine encyclopedia entitled the *Suda*. These

sources suggest that he was born in the southwest Anatolian city of Halicarnassus (in modern Turkey) and died in the south Italian city of Thurii. The presence of both Greek and Carian (relating to a region of Anatolia) names in his family indicates that he was probably of mixed Greek and Carian ancestry. Except for his being exiled after an unsuccessful attempt to oust the tyrant of Halicarnassus and his death at Thurii, the only known events of Herodotus's life are the travels he mentions in his work. These were extensive and included visits to Athens, Egypt, North Africa, southern Italy, and the Black Sea.

Herodotus is known to have written only one book: the *Histories*. When it was published in the 420s BCE, it was probably one of the longest, if not the longest, and most complex prose works that had been written in Greek to that time. Herodotus stated his purpose in the first sentence of the *Histories*: to preserve the memory of the great deeds of the Greeks and barbarians and to explain the reason they fought with each other.

Herodotus achieved his purpose by tracing in the first four books of the

Bust believed to be a portrait of Herodotus, Ancient Agora Museum, Athens. In antiquity the “Father of History” was called the “Father of Lies,” but modern scholars have confirmed his reliability and many of his fantastical accounts of events.

The only good is knowledge, and the only evil is ignorance. • **Herodotus (484?–430/420 BCE)**

Histories the rise of the Persian Empire from its foundation in the mid-sixth century BCE to the outbreak of the Ionian Revolt in 499 BCE. Accounts of the history and culture of the various peoples conquered by the Persians interspersed throughout the narrative provided a panoramic view of the world known to the Greeks. In the final five books he then narrated in detail the conflict between the Greeks and Persians from the Ionian Revolt to the failure of the Persian king Xerxes's great invasion of Greece in 480–479 BCE. Uniting his account was the idea that the conflict represented a struggle between Europe and Asia and freedom and slavery as represented by the leading peoples of each continent: the Greeks and the Persians.

Herodotus's work immediately became the standard Greek account of the Persian Wars. Thucydides and other Greek historians continued his work, but none tried to redo it. Already in antiquity, however, Herodotus's status as a historian was controversial, as evidenced by the tendency to refer to him not only as the "Father of History" but also as the "Father of Lies" because of the numerous fantastic stories in his work. The rehabilitation of Herodotus's reputation as a historian began during the Age of Discovery with the recognition of numerous parallels between his work and European explorers' accounts of the Americas. Further evidence of his reliability was provided by archaeological discoveries confirming the accuracy of many of his descriptions of non-Greek monuments and burial practices. Finally, recent scholarship has demonstrated close parallels between Herodotus's methods as described in the *Histories* and traditional oral historians in Africa and elsewhere, thereby vindicating his claim that his work was primarily based on two sources: his personal observations and critical evaluation of what people told him during his travels.

Herodotus's position as the founder of the Greek historiographic tradition is secure, as is his

contribution to world history. That contribution was threefold. He was the first to use the criterion of reliable evidence to distinguish historical time. He also introduced the idea of the succession of empires that provided the basic framework for European world histories until the nineteenth century CE. Most important, however, he recognized that all peoples have their own independent histories and established the principle that historians should rely on native sources to write the history of any people. Although Herodotus's practice was not always equal to his principles, and although his most important successor, Thucydides, narrowed the scope of mainstream Greek historiography to contemporary war and politics, the *Histories* continued to provide a model and fundamental source for world histories throughout antiquity.

Hinduism

Hindu culture began about 4000 BCE on the Indian subcontinent; today some 900 million followers worldwide practice Hindu traditions, or the “Vedic dispensation.” Early Vedic culture was founded on the premise that humans are not born equal, and it considered domestic and public rituals indispensable to the well-being of society and the individual. Pluralism was a hallmark of its religion, with many gods and goddesses invoked in Vedic hymns.

English scholars in the early nineteenth century coined the term *Hinduism* as a collective name for the indigenous religions of India. They added *-ism* to the designation *Hindu*, which goes back several thousand years to the Persians and the Greeks, who had so named the people living beyond the Indus River. It may be impossible to define Hinduism as one religion, but it makes perfect sense to speak of a Hindu culture and Hindu civilization. Over thousands of years there grew on the Indian subcontinent a distinctive culture embracing all spheres of human activity. From India it was carried to large parts of Southeast Asia, including Sri Lanka, Myanmar (Burma), Indonesia, and the Philippines. Ships coming from India via the Philippines may well have reached Central America centuries before Columbus. Today the various streams comprising Hinduism claim more than 900 million followers worldwide.

Origins

Hindus call their own tradition *Vaidika dharma*, “the Vedic dispensation.” Its original heartland was the Sapta Sindhava—the area watered by the seven great

rivers flowing into the Indus. Later this region came to be called the Punjab, the Five-River Country, after one river had dried out and another had changed its course. *Itihasa Purana*, a vast ancient narrative literature that is the repository for ancient Indian history, contains tales of the beginnings of humankind and of Hindu civilization, including long lists of dynasties going back several thousand years.

To account for the close affinity of many European and Indian languages, around 1860 British scholars invented the Aryan invasion theory. Not supported by literary or archaeological evidence but based purely on linguistic speculation, they asserted that a warrior people, coming from the West, invaded India and imposed their culture, their language, and their social structure on the indigenous population. The supporters of this theory equated this invading people with the Aryans mentioned in the Vedas, India’s ancient liturgical literature (c. 1500–1200 BCE). Such an invasion would have been quite a feat, considering that the indigenous population of India at that time is estimated to have been around 23 million. When in the 1920s the first major remnants of the Indus Valley civilizations were unearthed—ruins of large, ancient, well laid-out cities—these were first identified with the fortified places described in the Vedas as having been destroyed by the Aryans’ warrior-god Indra. It later emerged that these cities were not destroyed by foreign invaders but abandoned by 1750 BCE, probably because of drastic climate changes. The Sarasvati River, described in the Rig Veda as a mighty river, had completely dried out by 1900 BCE.

There is growing agreement today that the Vedic civilization originated around 4000 BCE or earlier in northern India itself (and not in the west) and that

the Indus civilization (c. 2500–1750 BCE, now called by some scholars the Sindhu-Sarasvati civilization), was part of it. When the settlements in Sapta Sindhava had to be abandoned, most of the inhabitants moved east into the densely wooded region of the land between the Yamuna and Ganges Rivers (called the Yamuna-Ganges Doab), which became the new center of Vedic civilization. Archaeologists affirm that there is no cultural break between the earlier and the later civilizations in North India.

The Hindu Holy Land

Hindu civilization was from the very beginning closely tied to the land that is present-day India. “The Motherland” has a unique emotional appeal for Indians: the physical features of the country are associated with the gods and goddesses, the religious practices, and the eschatological expectations of the Hindus. The Ganges (or, in Sanskrit and Hindi, Ganga), the Yamuna, the Narmada, the Kaveri are not only reservoirs of water and transportation ways, but also sources of inspiration and ritual purification: they are divinities to be worshipped. The towns and cities along their banks—Varanasi, Mathura, Nasik, Prayaga (Allahabad), and so on—are places where pilgrims congregate to obtain supernatural blessings and from which one can reach liberation. The Himalayas, the Vindhyas, the Ghats, and the Nilgiri Hills are the abodes of gods, sanctified by thousands of *rishis* (visionaries or sages) and *sannyasins* (renunciates) since

ages immemorial. Ancient and medieval India was dotted with numerous sacred groves—large uninhabited areas in which the gods dwelled and where nobody could harm an animal or a tree with impunity. Countless temples embellish India’s landscape, visibly transforming the country into a holy land, where gods dwell among humans.

Scriptures

Hindu scriptures have come down through the ages in two major streams: the Vedas and the Agamas. The Vedas are the literature of the religious professionals, to be memorized and recited by Brahmins only. They comprise the four Samhitas (collections of hymns: Rig Veda, Sama Veda, Yajur Veda, and Atharva Veda), a large number of Brahmanas (ritual texts), the Aranyakas (forest treatises) and Upanishads (mystical writings). The Agamas are the sacred literature of the people at large. The great epics—the *Ramayana* and the *Mahabharata*—are also important sources of Hindu religion: many Hindus consider the *Bhagavad Gita*, a section of the *Mahabharata*, to be an epitome of their religion. The Puranas, which are Bible-like sacred books, are widely read by Hindus from all classes. Texts such as the Vaisnava Samhitas, Saiva Agamas, and Shakta Tantras are considered to be divinely revealed by the followers of specific worship traditions. They contain creation narratives, genealogies of kings and patriarchs, myths of gods and goddesses, edifying stories, and eschatological lore. Based on these texts, poets and playwrights such as Kalidasa (flourished fifth century CE) and Bana (seventh century CE) produced dramatic literature of a high order in Sanskrit. Poet-saints such as Tulasidasa and Kambha (sixteenth century) created popular vernacular versions

Puja, the worship of great Hindu gods like Lord Siva, still involves old Vedic rituals.

of the classics, performed in plays and (since the advent of film) dramatized on screen to this very day.

The language of the most ancient literary documents of Hinduism, Vedic, is an archaic form of Sanskrit, the refined language standardized around 400 BCE by Panini. Sanskrit was called *deva vani*, the “language of the gods,” a sacred language. It became the language of Hindu scholarship as well as Hindu religious literature.

Rituals

Domestic and public rituals were a prominent feature of early Vedic culture, considered indispensable for the well-being of society and individuals. The praxis and the theory of *yajna* (sacrifice) can justly be called a science: hundreds of intricate and interrelated rules had to be memorized and observed. The construction of the altars required the solution of difficult arithmetic and geometric problems. The altars were built with special bricks arranged in a prescribed geometric

pattern, and were conceived of as symbols of the human body as well as of the universe: the 360 bricks of an altar represented the 360 days of the year and the 360 bones in the human body. Additionally, astronomical knowledge of a fairly high order was required to determine the right time for the performance of Vedic sacrifices, and ancient text explained how to determine the positions of celestial bodies at different times of the year.

The routine of fixed, or obligatory, rituals structured the course of the year and the lifecycle, creating a framework supporting communities and families. Rituals accompanied the change of seasons, as well as the stages in the development of persons: public offerings ensured the fertility of fields and domestic animals, while home rituals accompanied birth, adolescence, marriage, and death. Occasional, nonobligatory, rituals were available to give spiritual support in special circumstances and additional comfort to individuals. In later centuries, when *puja*, the worship of great gods like Vishnu and Siva associated with images and temples, became the predominant form of religion, the old Vedic rituals were not given up. Besides the *pujas* the performance of Vedic rites continues to this very day: Brahmins recite Vedic hymns at initiations, marriages, and last rites.

Many Hindus participate in daily temple *pujas* and partake of consecrated food. Major temple festivals are great public events for every village and town. The performance of numerous domestic rituals, such as offering food to the image of a deity or, in the evening, rotating a plate with burning pieces of camphor before the image, is still very widespread in India.

Music is an important part of Hindu rituals. Vedic hymns are recited according to a definite pattern of pitches. Instrumental and vocal music, together with ritual dance, are indispensable ingredient in temple worship.

Societal Hierarchy and Government

Traditional Hindu society functioned on the assumption that humans are not born equal and that their

Flowers serve as offerings in the *puja* (worship) of Ganesh, one of the best-known Hindu gods. Also called the Remover of Obstacles, Ganesh is usually portrayed as having the head of an elephant.

birth in different *varnas* (classes) defines their specific rights and duties. Brahmans, born from the Great Being's mouth, were the custodians of the Veda, the highest in rank. Kshatriyas, born from the chest, were rulers and warriors. Vaishyas, born from the belly—businesspeople, artisans, farmers, and clerks—had to provide the necessities of life for society at large. Sudras, originating from the feet, were to serve the upper three classes. Ati-sudras, the people below the Sudras, are known in English as “untouchables.” They were outside the pale of Hindu society proper and were relegated to work that was considered ritually polluting, such as skinning carcasses, cleaning latrines, and disposing of the dead. They were not allowed to dwell in the village proper and were not entitled to using amenities reserved for caste people. Today, in spite of legislation forbidding discrimination, they are still often exposed to disadvantage and mistreatment. Each of the four classes

comprise of hundreds of *jatis* (subcastes) that also observe ranking among each other.

Duties varied not only according to *varnas*, but also with respect to one's stage in life. Men of the upper three *varnas* were to spend the first twelve years after their initiation with a reputable teacher. They then had to marry and to produce children. After the children had grown up they were to live lives of simplicity and meditation, and finally they were to become renunciates and as homeless pilgrims were to visit holy places till death relieved them of the burden of their bodies. In reality, relatively few men actually ended their lives as homeless pilgrims.

An important element of the Hindu tradition was the theory and practice of government. Kings were usually Kshatriyas, but Brahmans had great influence as advisers and ministers. One of the aims of the Hindu awakening that began in the early twentieth

God has made different religions to suit different aspirations, times and countries . . . one can reach God if one follows any of the paths with wholehearted devotion. • Ramakrishna (1836–1886)

century was to reestablish Hindu dominion after centuries of rule by non-Hindus. The Hindu Mahasabha, the first modern Hindu political party, proclaimed in its manifesto: “Hindus have a right to live in peace as Hindus, to legislate, to rule themselves in accordance with Hindu genius and ideals and establish by all lawful and legal means a Hindu State, based on Hindu culture and tradition, so that Hindu ideology and way of life would have a homeland of its own” (Pattabhiram 1967, 217).

The Indian struggle for independence from the British in the twentieth century was fought by many for the purpose of reviving Hindu civilization. Jawaharlal Nehru (1889–1964), the first prime minister of India (1947–1964), advocated secular socialism and state-promoted industrialization, calling steel mills and hydroelectric dams the “temples of the new India,” but under his successors the revitalization of Hindu culture became a major issue.

In former centuries Hindu rulers built temples and supported religious endowments. Today government-appointed temple boards oversee the activities and budgets of most large temples. Businesspeople and industrialists, together with the followers of famous gurus, found new temples all over India. Since independence in 1947, more new Hindu temples have been built in India than in the five hundred years before, amongst them the well-known Birla Temple in New Delhi. Today more than 25 million Hindus live outside India. In Southeast Asia, Europe, North America, Africa, Australia, and Oceania hundreds of Hindu temples have been built, often replicas of famous Indian temples, with Hindu priests performing Hindu ceremonies. The Vishva Hindu Parishad, or World Association of Hindus, founded in 1964 in Mumbai, is active in India and among overseas Hindus protecting and promoting Hindu culture.

The Transmission of Tradition

Vedic religion was family based: specific branches of the Veda were preserved in individual families. The home was also a center for religious practices. The sacred hearth fire was not allowed to die out. Husband

and wife together had to perform the domestic rituals. Families were responsible for the lifecycle rituals. Young boys moved into the families of gurus, to be taught. The role of the guru reached great prominence when specific worship communities developed under the leadership of charismatic personalities, who often claimed to be the embodiment of a deity. These religious leaders helped to shape mainstream Hinduism and still exercise great influence on Hindus at large. They regulate the lives of their followers and reinterpret scriptures and traditional teachings. Their writings—especially the commentaries on the Upanishads, *Bhagavad Gita*, and the Brahma sutras—are the main texts for students of Hindu theology. In some circles Vedic tradition has remained intact—in others, it has not. Instead of leaving home with a guru, many boys in big cities receive the sacred thread at the appropriate age and begin being taught traditional ethics and lore by a senior relative or a Brahmin who is a family friend.

Pluralism was a hallmark of Hindu religion from its very beginning. Many gods and goddesses are invoked in Vedic hymns, and Hindus continue to worship a great variety of deities in their temples. There is no creed to which all Hindus subscribe and no one doctrine or practice that is common to all Hindus, except perhaps the nominal acceptance of the Vedas as revealed scripture and the belief in karma and rebirth.

Education

The initiation ceremony at which the sacred thread was given to a young boy (now increasingly again to young girls) was the “second birth” which entitled someone to receiving instruction. It was given to the three higher *varnas*: Brahmans, Kshatriyas, and Vaishyas. Sudras and Ati-sudras were excluded. Traditionally, education was a high priority for Brahmans, whose early life was devoted to study and for whom life-long education was a duty. In addition to learning from a guru in his home, a student could attend a school attached to an ashram or temple. The well-organized, publicly and privately sponsored ancient Indian universities, such as Taksasila (now

Taxila, established c. 700 BCE) in the Punjab, and Nalanda (traditionally dated to the sixth or fifth century BCE, though archaeological evidence points to establishment around the fifth century CE) and Vikramasila (established c. 800 CE) in Bihar, had thousands of teachers and tens of thousands of students. They taught not only the Vedas, but also the “eighteen sciences,” later supplemented by the “sixty-four arts.” The basic curriculum included linguistics, arts and crafts, medicine, logic and dialectics, and spirituality.

High ethical standards were expected both from students and teachers. Students not only had to pass stringent examinations to prove their aptitude, they also had to live an austere and pure life. Hindus believed in a balance of values, however, as expressed in the four “aims of life.” It was legitimate to acquire wealth and to enjoy life, but one also had to practice morality and religion and to seek final emancipation from the bonds of this existence in order to lead a fulfilled life.

Ayurvedic Medicine

Ayurvedic medicine, whose principles derive from the Vedas, was cultivated systematically from early on. It was mainly oriented towards preventing diseases and healing through herbal remedies. Good health was not only considered generally desirable, but also a precondition for reaching spiritual fulfillment. The practice of medicine as a form of charity was widely recommended and supported by Hindu rulers. It was considered a charitable act to provide medicine to the sick free of charge, and it was one of the activities in which monks were encouraged to participate. Two Indian medical handbooks, the result of centuries of development, became famous in the ancient world far beyond India: the *Caraka samhita* (dating from 200 BCE to 300 CE) and the *Sushruta samhita*. Ayurveda was also applied to animals and plants; there is an ancient handbook for professional gardeners and a text for cattle-veterinarians. Other texts deal with veterinary medicine relating to horses and elephants. Ancient India also had veterinary hospitals as well

as animal clinics. *Goshalas*, places in which elderly cattle are provided for, are still popular in some parts of India. The scientific value of Ayurvedic pharmacology is being recognized today by major Western pharmaceutical companies, who apply for worldwide patents on medicinal plants discovered and described in ancient Indian texts.

Philosophy

India does not know the division between philosophy and theology that characterizes much of modern Western intellectual history. It is natural for Hindus with an enquiring mind to analyze and investigate the teachings of their traditions, and professional philosophers with a Hindu background deal also with religious issues in a philosophically meaningful way. Hindu philosophical systems are not mere abstract constructs, but paths for the realization of the highest purpose of life. Among the qualifications required for beginning philosophical study is the earnest desire to find liberation from the sufferings of the cycles of rebirth and death, which are caused by ignorance of the true nature of reality.

Among the six orthodox systems of philosophy (*darsanas*) is Samkhya, which teaches a general theory of evolution based on the interactive polarity of nature and matter on the one hand with spirit and soul on the other. All reality is subsumed under five-times-five principles that originate from one substratum. The twenty-five categories to which Samkhya reduces the manifold world became widely accepted in Hindu thought. A second *darsana*, the Yoga system of Patanjali, which dates to around 200 BCE, is wholly based on it.

Vaisesika, the third of the six *darsanas*, offers a theory of atomism that is possibly more ancient than that of the Greek philosopher Democritus (c. 460–c. 370 BCE), as well as a detailed analysis of qualities and differences. It also developed the notion of impetus.

Adhyatma vidya (the term refers to spirituality in general—not a specific system), the spiritual or inner sciences, which relate to Brahma, the supreme

reality, was considered the highest: it employed personal experience, a coherent epistemology, and the exegesis of revealed utterances. The Upanishads mention thirty-two *vidyas*, paths leading to the goal of all science. The knowledge aimed at through these was of a particular kind, involving a transformation of the student. The ideas of the Upanishads were further developed into the system of Vedanta philosophy laid down mainly in commentaries on the Brahma sutras ascribed to Badarayana (first centuries CE). Beginning with Shankara (eighth century CE) and continuing with Ramanuja (c. 1017–1137) and Madhava (1296?–1386?), the greatest spiritual minds of India have endeavored to cultivate that science of the eternal reality of the spirit.

Hinduism in World History

Membership in the Hindu community was for many centuries restricted to those who were born from Hindu parents and who had undergone the various sacraments that made a Hindu a full member of the Hindu community both here and in the beyond. Hinduism was always a “world religion” due to the fact that India has always been a densely populated, large country and thus home of a considerable part of humankind. In its heyday (prior to the Muslim invasion which began in the eighth century CE) India attracted students and pilgrims from all over Asia who studied at the large indigenous universities or visited holy places associated with such figures as the Buddha.

During the first half of the first millennium Hinduism also spread into most of Southeast Asia, as mentioned earlier. This period was followed by a prohibition to cross “the black seas” under threat of loss of caste. This prohibition was most likely a move to protect the Hindu community from erosion after the Muslims had invaded India and pressured Hindus to convert to Islam. Hindu thought and culture, however, were adopted by many foreigners who came into contact with India during this time. With the establishment of British rule in India in the eighteenth century and the advent of Christian

missions, Hindus’ interest in spreading their religion abroad was awakened: the much-celebrated presentations of Swami Vivekananda (1863–1902) at the World Parliament of Religions in Chicago 1893 and his subsequent journey through the United States and Great Britain resulted in the establishment of Vedanta centers in many places and a fairly widespread interest in Hinduism. The coming of ever more Hindu swamis and gurus to the West since the 1960s familiarized thousands with sectarian Hinduism and attracted many Westerners to Hindu religious communities. It was no longer deemed necessary to have been born Hindu, one could become a Hindu by accepting Hindu doctrines and ritual practices and by receiving initiation from a qualified Hindu guru.

By now millions of Hindus have settled all over the world and have brought Hinduism as their inherited faith to the places where they now live. Scientists with a Hindu background often endeavor to integrate their scientific specialties with Hindu traditional thought and thus consciously promote Hinduism as a modern faith. New Age literature, popular among the educated all over the Western world, is replete with Hindu ideas and images, which it presents as having anticipated modern scientific discoveries and insights. Both by virtue of the large number of adherents and the sophistication of its culture and philosophy, Hinduism is bound to be a major influence on the global civilization of the future.

History, Maritime

Maritime history is the study of the role mariners play in creating and maintaining commercial and cultural relationships between different parts of the world—in peace and in war. Commerce at sea and naval warfare are central to the development, structure, and expansion of local, regional, and international relationships.

Mariners have played a formative and often determining role in shaping the world as we know it, not just among people dependent daily on the sea for their livelihood, but for those who live deep in continental interiors well away from the tang of salt air. The study of maritime history is crucial to a proper understanding of the rise and fall of civilizations, human migration, and the resulting spread of language, religion, technology, religions and political systems, and flora and fauna across the world. It is equally important for understanding interactions over relatively short distances, both in enclosed seas like the Mediterranean and in continental interiors accessible by rivers and lakes.

At the beginning of the twenty-first century, about 90 percent of world trade travels by water. Carrying goods by ship is in most instances more energy efficient than transporting goods overland. The energy required to move a ton of freight one kilometer by ship is about one-fifth that required to move it by train and as little as one-tenth that required to move it by truck. Ground transport has been an attractive alternative for shippers only since the development of railways, the internal combustion engine, and hard-top roads in the past two centuries. Until well into the twentieth century it could take as long for a ship's cargo to cross a pier as it did to cross the ocean.

The Start of Maritime Endeavor

Because of the diverse environments in which maritime endeavor takes place, the erratic diffusion of technology, and differences in approach to commerce, few generalizations about the course of maritime history are possible. People have been going to sea for tens of thousands of years: Australia was settled by sea from Indonesia fifty millennia ago, there are stone carvings of Scandinavian vessels from ten thousand years ago, and Scotland's Outer Hebrides were settled about 4000 BCE. Broadly speaking, before 1500 BCE, there was considerable regional interaction across Eurasia, but several maritime cultures evolved in relative isolation.

In terms of oceanic seafaring, the most impressive achievement occurred in Oceania, where between 1500 BCE and 1500 CE people settled virtually all the habitable islands of Polynesia, Melanesia, and Micronesia from the Solomon Islands to Rapa Nui (Easter Island) and New Zealand to Hawaii. To do this, they developed a diverse repertoire of vessels unlike anything found in Eurasia or elsewhere. Although they developed virtually no navigational instruments or written instructions, they navigated by a combination of celestial observation, reading winds and swells, and observing the habits of fish, sea mammals, and birds, a body of information transmitted by oral tradition.

Sails were apparently unknown in the Americas before 1500—except perhaps to mariners who traded between Ecuador and the Pacific coast of Mexico. But traders paddled dugouts and canoes on sea routes from New York to Newfoundland and inland to the Great Lakes and Mississippi. Less well documented

“Ship of Hatasu laden with produce from Punt.” From *Egypt: Descriptive, Historical and Picturesque* by Georg Ebers. London: Cassell, 1881–1882.

are the achievements of the Arawak and Carib of the Caribbean, and the coastal people of the Pacific Northwest, southern Alaska, and the Aleutians. Farther north, Arctic and sub-Arctic mariners traveled, fished, and whaled from skin boats along the northern coasts of Eurasia and North America.

The Ancient World

The first civilizations whose use of ships and boats can be said to have contributed to or reflected the advanced states of their technology and political organization are found from the eastern Mediterranean to the western Indian Ocean in the third millennium BCE. On the Nile, the mastery of shipbuilding and navigation was crucial to the political, economic, and social unification of Egypt. The earliest depiction of a sail is on a late-fourth-millennium vase found in Upper Egypt. By the reign of Sneferu (c. 2600 BCE), the Egyptians were sailing regularly to the Levant for cedar wood. They also traded on the Red Sea to Punt (Somalia, perhaps) for myrrh, gold, electrum (an alloy of gold and silver), incense, and cosmetics. Egyptian records also include the first accounts of fighting between ships, in twelfth- and thirteenth-century BCE accounts of the invasion of the Sea People. The Egyptians also used the Nile to transport thousand-ton blocks of stone hundreds of kilometers from their quarries to the building sites of the pyramids.

Comparable activities advanced domestic and foreign commerce, as well as state formation and expansion, among Egypt's Bronze Age (third to second millennia BCE) contemporaries, notably Minoan Crete (and later Mycenaean Greece) and the Levantine port cities of Ugarit, Byblos, and Tyre. Mesopotamians

used boats on the Tigris and Euphrates rivers and the network of canals they built for flood control, irrigation, and transportation, and in the third millennium BCE there was long-distance trade under sail between the Persian Gulf and the Indus Valley civilizations. Shipping laws in the Code of Hammurabi anticipate later Mediterranean law and custom, and the third-millennium Epic of Gilgamesh includes the archetypal stories of the ark and flood, and of the sea-wandering hero. The former are best known from the later Hebrew Bible, while Homer's Odysseus (early first millennium BCE) is the best-known model for the latter. Neither Gilgamesh nor Odysseus can be identified with specific historical figures, but the geography of the stories is grounded in the experience of the authors' respective contemporaries.

The first examples of maritime expansion on a scale that allowed for sustained two-way transmissions of culture, as distinct from one-way migrations or low-volume trade, come from the Mediterranean world of the early first millennium BCE. In the ninth century BCE, the Phoenicians established colonies at Carthage, in the western Mediterranean, and on the Atlantic coasts of the Iberian Peninsula and Morocco, and the Greeks began to colonize the Black Sea and northern Mediterranean. The Persian invasions of Greece in the early 400s BCE were defeated in part by the Athenian victory at the naval battle of Salamis, which helped foster the concept of a dichotomy between maritime powers and land-based powers, although such distinctions are rarely clear-cut.

Maritime matters assumed ever greater importance in the following centuries, and the Pharos (lighthouse) at Alexandria—the city that Alexander of Macedon (Alexander the Great) founded and which remains

a major port 2,300 years later—and the Colossus marking the entrance to Rhodes harbor were among the wonders of the ancient world. During the Hellenistic period, Alexander's successors embarked on the world's first naval arms race, a major source of friction being the control of eastern Mediterranean timber supplies, a competition for naval resources not unlike that which made Baltic forests a focus of attention in the eighteenth and nineteenth centuries CE, or Persian Gulf oil in the twentieth and twenty-first centuries.

Rome wrested control of the western Mediterranean from the Carthaginians during the Punic Wars of the third and second centuries BCE. Although Roman authors disdained the sea, the empire's survival depended on secure shipping lanes. Pompey the Great eradicated Mediterranean piracy in the first century BCE, Octavian's victory at Actium was the defining battle of the Civil War, Rome fed on grain imported from Sicily, Spain, and Egypt, and the empire's northern borders held only so long as the Romans controlled navigation on the Rhine and Danube rivers and the English Channel. When Germanic and Slavic tribes reached the Mediterranean in the fifth century CE, the different fortunes of the Roman West and Byzantine East were due partly to the fact that the Byzantines had an effective navy.

A coherent picture of maritime activities in Asian waters between India and China emerges only around 1000 BCE, and does not come into sharp relief for another five centuries. There are glimpses of Indian maritime life in Hindu writings like the Rig Veda and the Upanishads (late second millennium BCE) and Buddhist scriptures, as well as decrees from the reign of India's Asoka (third century BCE). Alexander had renewed the Mediterranean world's interest in the Indian Ocean, and the most detailed accounts of trade are from Greek and Roman geographies—Ptolemy described the world as far east as the Malay Peninsula—and merchants' handbooks from the second century BCE to the second century CE. Despite western participation in Asian sea trade, indigenous traders were of far greater consequence. In addition to their traffic in material goods, maritime merchants

carried Buddhism and Hinduism from India to Southeast Asia. The importance of Indian merchants in mainland Southeast Asia is illustrated in two foundation stories for the kingdom of Funan, a productive rice-growing region that dominated east–west trade from Oc Eo, a port on the Gulf of Thailand near the Mekong River.

As was true in Egypt and Mesopotamia, Chinese maritime endeavor began on the rivers that they tamed by building canals for irrigation and transportation. Although the Chinese traded with Korea and Japan from an early date, they were more attracted to the southern trade, which began with the absorption of the southern Yue people in the fourth century BCE, and with their first forays against Vietnam, some of which were carried out by sea. By the time Funan declined in the fifth century CE, Chinese monks and traders were regularly sailing through Southeast Asia as far as Ceylon (Sri Lanka) and other lands within the Buddhist world.

The Medieval Period

The rise of Islam in the seventh century led to a reorientation of Mediterranean trade, signaled especially by the Muslim capture of Alexandria and the rerouting of Egypt's grain trade from Byzantium to Jidda, Mecca's port on the Red Sea. The Muslim caliphs relied on indigenous maritime communities in the eastern Mediterranean to man their fleets. Despite several naval assaults, the Muslims did not take Byzantium; but they did capture a large portion of the east–west trade in a Mediterranean world divided between a Christian north and Muslim south. The balance of power began to shift again around the year 1000, when Italian merchants penetrated the Mediterranean and Black Sea trading networks of the Byzantine Empire. The Venetians were well placed to capitalize on the Crusades at the end of the century. Although the First Crusade reached the Levant overland, the coastal Crusader states required reinforcement by sea, and Venetian, Genoese, Pisan, and other merchants secured favorable privileges for the flourishing Asian trades in exchange for their services.

You tell the men there are four ways of doing things on this ship: the right way, the wrong way, the Navy way, and my way. They do things my way, and we'll get along just fine. • **Humphrey Bogart (1899–1957) as Lt. Commander Philip Francis Queeg in *The Caine Mutiny***

One reason for the decline of Roman rule in the British Isles in the fourth and fifth centuries had been pressure from Germanic raiders from north-west Europe. The maritime expansion of northern peoples accelerated under the Vikings, whose rapid and far-flung expansion was facilitated by the adoption of the sail, which reached the Baltic in about the seventh century. The Vikings raided the British Isles and the fringe of Europe as far as Muslim Spain. They crossed the North Atlantic to Iceland (in the wake of Irish monks), Greenland, and Newfoundland. The rivers of eastern Europe carried them from the modern Baltic states, Poland, and Russia to the Caspian and Black Seas. Between the tenth and thirteenth centuries, many Vikings served in the Byzantine emperor's elite Varangian Guard. The most celebrated of these was Harald Hardradi, who in 1066, as king of Norway, invaded England with a fleet of three hundred ships. He was defeated by the Anglo-Danish king Harold Godwinson at the Battle of Stamford Bridge, near York. Two weeks later, Harold Godwinson was killed at Hastings in battle with the army of William (the Conqueror), Duke of Normandy. A descendant of the first Viking raider/settlers of northern France, William had crossed the English Channel with some nine hundred ships to claim the English throne.

In many respects, William's victory marks the end of the Viking Age. Over the following century, the Baltic and North Sea trades passed to Germanic merchants who sailed under a loose confederation known as the Hanseatic League and specialized in bulky commodities such as grain, timber, fish, and wool, carried in capacious ships known as cogs. The prosperity of northern Europe would depend on such trade for centuries to come.

Of greater moment in this period was the Islamic expansion, via Arab and Persian sea traders, down the coast of East Africa as far as Mozambique and eastward to China. During the nearly seven centuries spanned by the Tang and Song dynasties (618–1279), China's overseas trade flourished. The expatriate Arab, Persian, Armenian, Jewish, Christian, Malay, and Japanese traders who thronged the ports of Guangzhou,

Quanzhou, and Yangzhou numbered in the hundreds of thousands. Periodic bouts of violent xenophobia, in which tens of thousands of foreigners were killed, compelled these foreigners to withdraw temporarily to northern Vietnam.

Increased traffic between the China seas and the Indian Ocean affected the politics of Southeast Asia. By the seventh century, ships had abandoned the Southeast Asian coastal route to sail directly across the South China Sea, and the Srivijayan states straddling the Strait of Malacca dominated the route between the Far East and the Indian Ocean. East-west trade also enriched southern India and the Maldiv Islands. In the eleventh century, the expansionist Chola kingdom of southern India invaded Srivijaya, 2,400 kilometers east across the Bay of Bengal. The Cholas could not capitalize on their victory at such a distance, but the emerging state of East Java was able to supersede its weakened neighbor. In their ascendancy, the Javanese inaugurated the first large-scale exploitation of the Spice Islands (Melaku) in eastern Indonesia. Thanks to the prosperity at either end of maritime Asia, cloves, nutmeg, and mace became staples of trade from Song China to Fatimid Egypt and the Mediterranean.

The Early Modern Period

Merchant states jockeying for control of Mediterranean and European trade routes spread a common commercial culture across Christian Europe. Their success depended on the outcome of this period's two major struggles: the Christian advance against Muslim Spain, and the Muslim expulsion of Crusaders from the Levant in 1291. While the latter forced Venetian, Genoese, and other Christian merchants to seek their fortunes elsewhere, the loosening of Muslim control in the Strait of Gibraltar literally opened a new outlet for their commercial aspirations. The start of direct sea trade between the Mediterranean and Northern Europe in the 1270s was a catalyst for economic growth in northwest Europe, which gradually came to rival the Mediterranean in commercial prosperity.

As a result of increased maritime commerce between northern Europe and the Mediterranean, shipbuilding underwent several crucial changes that resulted in the development of the first generation of full-rigged ships in the fifteenth century. These large, strongly built carracks, or *naos*, were built around a skeletal framework, rigged with a combination of square sails (set perpendicular to the centerline of the hull) and fore-and-aft lateen sails, and carried centerline rudders instead of side-mounted steering oars. In addition to having increased carrying capacity and operational endurance, these carracks could mount heavy ships' guns, the use of which altered the nature of commerce and naval warfare.

Important though developments in the European and Mediterranean world were in facilitating Europe's overseas expansion, the lure of Asia's wealth was no less significant. Indian merchants from Gujarat (northwest India) and modern Bangladesh had long composed the major foreign trading community in Southeast Asia. When these states were converted to Islam in the 1200s, the religion and its associated cultural norms—including language and law—spread easily through the networks of trade to the east. By the end of the fifteenth century, Islam was firmly established in maritime Southeast Asia—the first western monotheistic religion to take root east of India.

At the start of China's Yuan dynasty, Khubilai Khan launched four overseas invasions: of Japan (1274 and

1281), Vietnam (1283), and East Java (1291). None was successful, but the expedition against Java helped pave the way for the emergence there of the Majapahit Empire that dominated the trade of Island Southeast Asia for two centuries. Between 1405 and 1433, the Ming dynasty exercised more immediate influence on the region. During this period, seven Chinese fleets under the Muslim eunuch Zheng He passed through the region en route to Indian Ocean ports from Ceylon to East Africa, the Red Sea, and the Persian Gulf. With crews numbering in the tens of thousands, these fleets suppressed piracy, introduced coinage as a medium of exchange in Southeast Asia, and bolstered the importance of the Muslim communities there. Although Chinese overseas commerce was officially banned in the mid-1400s, the twin movements of Muslim and Chinese merchants through Southeast Asia were the two most significant factors behind the emerging prosperity that attracted European interest at the end of the fifteenth century.

Europe's conquest of the Atlantic began with the start of direct maritime trade between the Mediterranean and northern Europe in the thirteenth century. Within two hundred years, Europeans had settled Madeira, the Azores, and the Canary and Cape Verde Islands. Motivated by a combination of ideology and profit characteristic of much subsequent European expansion, in the mid-1400s Portugal's Prince Henry ("the Navigator") promoted the exploration

of the coast of West Africa, a source of gold, slaves, and cheap pepper. These efforts led to the search for a sea route to the Indies, which culminated in the epochal voyages of Christopher Columbus's transatlantic crossing (1492), Vasco da Gama's opening of a sea route between Europe and the Indian Ocean via southern Africa (1497–1499), Ferdinand Magellan's and Juan Sebastian del Cano's east–west circumnavigation of the globe (1519–1521), and Andrés de Urdaneta's discovery of a west–east route across the Pacific (1565). The age of Columbus and his contemporaries (including shipwrights, bankers, cartographers, and gun-founders) is a defining point in world history. But the achievements of the age were the result of collective and cumulative experience, not of individual inspiration. Moreover, progress was hard won; mortality rates for sailors were high and there were many failures, notably the search for the Northwest and Northeast Passages to the Orient.

The Birth of Global Trade

Approaches to maritime trade differed according to a variety of factors. When the Spanish reached the Americas, they encountered no preexisting maritime commercial system, which helps account for the explosive if haphazard way their American Empire grew. In Asia, the Portuguese sailed into a mature commercial network the keys to which they learned early on. Although the Portuguese crown monopolized the spice trade and issued passes for indigenous traders, the Portuguese never dominated all regional trades and many found it more lucrative to participate in the so-called country trades within Asia rather than on the long-distance routes between Asia, Africa, Portugal, and Brazil. There were comparable differences of approach to trade between the Dutch and English in the seventeenth century. No sooner had the Dutch jurist Hugo Grotius articulated a philosophy of free trade in *Mare Liberum*, to counter the Portuguese monopoly, than he helped justify Dutch monopolies in Asia directed specifically against the English, who fell back on trade in high-volume, low-value Indian goods. Both the Dutch and English East

India companies would lay the groundwork for their respective governments' nineteenth-century colonial policies.

The movement of people on a scale sufficient to create social transformation through the transmission of language, religion, and material culture, as well as crops and flocks, accelerated after 1500. The most important vectors for cultural change were the mass movement of African slaves (between the sixteenth and nineteenth centuries), European transatlantic and Australian emigrants (through the twentieth century), and Chinese and Indian coolie laborers transported to Africa and Latin America (nineteenth and twentieth centuries).

In purely commercial terms, intraregional trades remained more important than long-distance ones. Chinese shipping carried the bulk of Asian trade until the nineteenth century, while the maritime integration of northern and southern Europe that began only two centuries before Columbus continued vigorously throughout this period. The bulk of Dutch wealth derived not from the Indies, but from European trades and fisheries. Europeans also dominated the Atlantic world, a rapidly evolving commercial and cultural space bounded by Europe, West Africa, and the Americas, where their influence was indelible.

Starting in the eighteenth century, Europeans undertook a wave of exploratory voyages animated by a spirit of scientific inquiry, though their objectives remained practical: safe navigation, new markets, and the desire to make allies or conquests to forestall the advance of rivals. In the 1760s, a French expedition under Louis-Antoine de Bougainville included ethnographers, zoologists, and botanists, an approach emulated by England's James Cook and his successors. Britain and France sustained active programs of exploration in the Pacific that continued through the Napoleonic Wars, after which the Russians and Americans were active in the business of maritime exploration. Russian efforts were ancillary to the country's eastward expansion across Siberia and Alaska, while the Americans were motivated by rivalry with the British in the Pacific Northwest and Pacific whaling grounds. Efforts to find the Northwest

and Northeast Passages also resumed in the nineteenth century; the latter was transited in 1878–1879, the former in 1903–1906. The coastal exploration of Antarctica began around the turn of the twentieth century. At the same time, prompted by the need to lay submarine cables and to study the health and potential of commercial fisheries, and later by the need for submarine mining and environmental monitoring and atmospheric research, scientists turned to the exploration of the oceans themselves.

The Steam Age

The advent of commercially viable steam navigation—signaled by the launch of Robert Fulton’s *North River Steam Boat* in 1807—followed by the development of iron and steel shipbuilding, transformed the world. It would take thirty years for steam to be adapted to ocean shipping, but in the meantime steam vessels capable of stemming powerful river currents did as much to open continents as they would to connect them.

The development of the steamship coincided with the Pax Britannica, which was guaranteed by Britain’s overwhelming maritime superiority. The Royal
